(54) Title: PROMOTER

(57) Abstract

The *in vivo* expression in the aleurone cells of a cereal of a conjugate is described. The conjugate comprises a GOI (gene of interest) and a particular Ltp (lipid transfer protein) promoter - namely the Ltp2 gene promoter. The conjugate is stably integrated within the cereal's genomic DNA.

PROMOTER

The present invention relates to a promoter and to a conjugate comprising the same. The present invention also relates to the use of the promoter for stage- and tissue- specific expression of a gene of interest (GOI). The present invention also relates to the genomic nucleotide sequence of, and isolation of, the promoter.

In particular the present invention relates to a promoter for a lipid transfer protein (Ltp) gene known as the Ltp2 gene. The present invention also relates to the application of this Ltp2 gene promoter to express a GOI specifically in the aleurone layer of a monocotyledon - especially a transgenic cereal seed - more especially a developing transgenic cereal seed.

A mature cereal seed contains two distinct organs: the embryo - which gives rise to the vegetative plant - and the endosperm - which supports the growth of the emerging seedling during a short period of time after germination. The endosperm, which is the site of deposition of different storage products such as starch and proteins, is further sub-divisible into a peripheral layer of living aleurone cells surrounding a central mass of non-living starchy endosperm cells.

The aleurone cells differentiate from primary endosperm cells early during seed development or between 10 to 21 days after fertilization. The aleurone layer and embryo share many similarities in their gene expression programmes. They are the only cereal seed tissues that survive the desiccation process during seed maturation and they both have active gene transcription during seed germination.

The aleurone layer of cereal seeds comprises specialized cells that surround the central starchy endosperm, i.e. the site for starch and protein accumulation in the developing seed (Bosnes *et al.*, 1992, Olsen *et al.*, 1992). During seed germination, the cells of the aleurone layer produce amylolytic and proteolytic enzymes that degrade the storage compounds into metabolites that are taken up and are used by the growing embryo. Two aspects of aleurone cell biology that have been intensively studied are the genetics of anthocyanin pigmentation of aleurone cells in maize (McClintock, 1987) and the hormonal regulation of gene transcription in the aleurone layer of germinating barley seeds (Fincher, 1989).

Using transposon tagging, several structural and regulatory genes in the anthocyanin synthesis pathway have been isolated and characterized (Paz-Ares *et al.*, 1987; Dellaporta *et al.*, 1988). In barley, alpha-amylase and beta-glucanase genes that are expressed both in the aleurone layer and embryos of mature germinating seeds have been identified (Karrer *et al.*, 1991; Slakeski and Fincher, 1992). In addition, two other cDNAs representing transcripts that are differentially expressed in the aleurone layers of developing barley grains have been isolated. These are CHI26 (Lea *et al.*,1991) and pZE40 (Smith *et al.*, 1992). For none of these gene products has it been shown in transgenic cereal plants that the promoter directs expression in just the aleurone layer of developing grains.

Non-specific lipid transfer proteins (nsLtp's) have the ability to mediate *in vitro* transfer of radiolabelled phospholipids from liposomal donor membranes to mitochondrial acceptor membranes (Kader *et al.*, 1984; Watanabe and Yamada, 1986). Although their *in vivo* function remains unclear, nsLTPs from plants have recently received much attention due to their recurrent isolation as cDNA clones representing developmentally regulated transcripts expressed in several different tissues. A common feature is that, at some point in development, they are highly expressed in tissues producing an extracellular layer rich in lipids. Thus, transcripts corresponding to cDNAs encoding 10 kDa nsLTPs have been characterized in the tapetum cells of anthers as well as the epidermal layers of leafs and shoots in tobacco (Koltunow *et al.*, 1990; Fleming *et al.*, 1992), and barley aleurone layers (Mundy and Rogers, 1986; Jakobsen *et al.*, 1989).

In addition, a 10 kDa nsLTP was discovered to be one of the proteins secreted from auxin-treated somatic carrot embryos into the tissue culture medium (Sterk *et al.*, 1991). Based on *in situ* data demonstrating that the Ltp transcripts are localized in the protoderm cells of the somatic and zygotic carrot embryo and in the epithelial layer of the maize embryonic scutellum, it was suggested that *in vivo* nsLTPs are involved in either cutin biosynthesis or in the biogenesis and degradation of storage lipids (Sossountzov *et al.*, 1991; Sterk *et al.*, 1991).

A nsLTP in *Arabidopsis* has been localized to the cell walls lending further support to an extracellular function if this class of proteins (Thoma *et al.*, 1993).

PCT WO 90/01551 mentions the use of the aleurone cells of mature, germinating seeds to produce proteins from GOIs under the control of an alpha-amylase promoter. This promoter is active only in germinating seeds.

Recently, using a standard *in vitro* Ltp assay, two 10 kDa and one member of a novel class of 7 kDa nsLtp's were isolated from wheat seeds (Monnet, 1990; Dieryck *et al.*, 1992). The sequence of this 7 kDa wheat nsLtp protein shows a high degree of similarity with the predicted protein from the open reading frame (ORF) of the Bz11E cDNA, which had been isolated in a differential screening for barley aleurone specific transcripts (Jakobsen *et al.*, 1989). However, the amino acid sequence of this polypeptide showed only limited sequence identities with the previously sequenced 10 kDa proteins. In sub-cellular localisation studies using gold labelled antibodies one 10 kDa protein from Arabidopsis was localised to the cell wall of epidermal leaf cells. The presence of a signal peptide domain in the N-terminus of the open reading frames of all characterised plant ns-LTP cDNAs, also suggests that these are proteins destined for the secretory pathway with a possible extracellular function.

Olsen *et al.* in a paper titled "Molecular Strategies For Improving Pre-Harvest Sprouting Resistance In Cereals" published in 1990 in the published extracts from the Fifth International Symposium On Pre-Harvest Sprouting In Cereals (Westview Press Inc.) describe three different strategies for expressing different "effector" genes in the aleurone layer and the scutellum in developing grains of transgenic plants. This document mentions 4 promoter systems - including a system called B11E (which is now recognised as being the same as the Ltp2 gene promoter). There is no sequence listing for B11E given in this document.

Kalla *et al.* (1993) in a paper titled "Characterisation of Promoter Elements Of Aleurone Specific Genes From Barley" describe the possibility of the expression of anti-sense genes by the use of promoters of the aleurone genes B22E, B23D, B14D, and B11E (which is now shown to be the same as Ltp2).

The Kalla *et al.* (1993) paper gives a very general map of the Ltp2 gene promoter. The transient expression results showed very low levels of expression of the reporter gene.

A sequence listing of the Ltp2 gene was available as of 23 December 1992 on the EMBL database.

One of the major limitations to the molecular breeding of new varieties of crop plants with aleurone cells expressing GOIs is the lack of a suitable aleurone specific promoter.

At present, the available promoters - such as the CaMV 35S, rice actin and maize alcohol dehydrogenase - all are constitutive. In this regard, they are non-specific in target site or stage development as they drive expression in most cell types in the plants.

Another problem is how to achieve expression of a product coded for by a GOI in the aleurone layer of the endosperm that gives minimal interference with the developing embryo and seedling.

It is therefore desirable to provide aleurone specific expression of GOIs in cereal such as rice, maize, wheat, barley and other transgenic cereal plants.

Moreover it is desirable to provide aleurone specific expression that does not lead to the detriment of the developing embryo and seedling.

According to a first aspect of the present invention there is provided a Ltp2 gene promoter comprising:

the sequence shown as SEQ. I.D. 1, or

a sequence that has substantial homology with that of SEQ. I.D. 1, or

a variant thereof.

According to a second aspect of the present invention there is provided a conjugate comprising a GOI and a Ltp2 gene promoter as just defined.

According to a third aspect of the present invention there is provided an in vivo expression system comprising a conjugate comprising a GOI and a Ltp2 gene promoter as just defined wherein the conjugate is integrated, preferably stably integrated, within a monocotyledon's (preferably a cereal's) genomic DNA.

According to a fourth aspect of the present invention there is provided a transgenic cereal comprising a conjugate comprising a GOI and a Ltp2 gene promoter as just defined wherein the conjugate is integrated, preferably stably integrated, within a cereal's genomic DNA.

According to a fifth aspect of the present invention there is provided the in vivo expression in the aleurone cells of a monocotyledon (preferably a cereal) of a conjugate comprising a GOI and a Ltp2 gene promoter as just defined; wherein the conjugate is integrated, preferably stably integrated, within the monocotyledon's genomic DNA.

According to a sixth aspect of the present invention there is provided a method of enhancing the in vivo expression of a GOI in just the aleurone cells of a monocotyledon (preferably a cereal) which comprises stably inserting into the genome of those cells a DNA conjugate comprising a Ltp2 gene promoter as just defined and a GOI; wherein in the formation of the conjugate the Ltp2 gene promoter is ligated to the GOI in such a manner that each of the myb site and the myc site in the Ltp2 gene promoter is maintained substantially intact.

According to a seventh aspect of the present invention there is provided the use of a myb site and a myc site in an Ltp2 gene promoter to enhance in vivo expression of a GOI in just in the aleurone cells of a monocotyledon (preferably a cereal) wherein the Ltp2 gene promoter and the GOI are integrated into the genome of the monocotyledon.

According to an eighth aspect of the present invention there is provided a method of enhancing the in vivo expression of a GOI in just the aleurone cells of a monocotyledon (preferably a cereal) which comprises stably inserting into the genome of those cells a DNA conjugate comprising a Ltp2 gene promoter as just defined and a GOI; wherein in the formation of th conjugate the Ltp2 gene promoter is ligated to the GOI in such a manner that any ne of the Sph1 site, the AL site or the DS site in the Ltp2 gene promoter is (are)

maintained substantially intact. The Sph1 site, the AL site and the DS site are defined later.

Preferably the promoter is a barley aleurone specific promoter.

Preferably the promoter is for a 7 kDa lipid transfer protein.

Preferably the promoter is used for expression of a GOI in a cereal seed.

Preferably the promoter is used for expression of a GOI in a monocotyledonous species, including a grass - preferably a transgenic cereal seed.

Preferably the cereal seed is anyone of a rice, maize, wheat, or barley seed.

Preferably the promoter is the promoter for Ltp2 of *Hordeum vulgare*.

Preferably at least one additional sequence is attached to the promoter gene or is present in the conjugate to increase expression of a GOI or the GOI.

The additional sequence may be one or more repeats (e.g. tandem repeats) of the promoter upstream box(es) which are responsible for the aleurone specific pattern of expression of Ltp2. The additional sequence may even be a *Sh1*-intron.

The term "GOI" with reference to the present invention means any gene of interest - but not the remainder of the natural Ltp2 gene for the cereal in question. A GOI can be any gene that is either foreign or natural to the cereal in question.

Typical examples of a GOI include genes encoding for proteins giving for example added nutritional value to the seed as a food or crop or for example increasing pathogen resistance. The GOI may even be an antisense construct for modifiying the expression of natural transcripts present in the relevant tissues.

Preferably the GOI is a gene encoding for any one of a protein having a high nutritional value, a *Bacillus thuringensis* insect toxin, or an alpha- or beta- amylase or germination induced protease antisense transcript.

The term "a variant thereof" with reference to the present invention means any substitution of, variation of, modification of, replacement of, deletion of or the addition of one or more nucleic acid(s) from or to the listed promoter sequence providing the resultant sequence exhibits aleurone specific expression.

The term "substantial homology" covers homology with respect to at least the essential nucleic acids of the listed promoter sequence providing the homologous sequence exhibits aleurone specific expression. Preferably there is at least 80% homology, more preferably at least 90% homology, and even more preferably there is at least 95% homology with the listed promoter sequence.

The term "maintained substantially intact" means that at least the essential components of each of the myb site and the myc site remain in the conjugate to ensure aleurone specific expression of a GOI. Preferably at least about 75%, more preferably at least about 90%, of the myb or myc site is left intact.

The term "conjugate", which is synonymous with the terms "construct" and "hybrid", covers a GOI directly or indirectly attached to the promoter gene to from a Ltp2-GOI cassette. An example of an indirect attachment is the provision of a suitable spacer group such as an intron sequence, such as the *Sh1*-intron, intermediate the promoter and the GOI.

The present invention therefore provides the novel and inventive use of an aleurone specific promoter - namely the use of the Ltp2 gene promoter, preferably the Ltp2 gene promoter from barley.

The main advantage of the present invention is that the use of the Ltp2 gene promoter results in specific aleurone expression of a GOI in the aleurone layer(s) of cereals such as rice, maize, wheat, barley and other transgenic cereal seeds, preferably maize seed.

It is particularly advantageous that the expression is both stage- and tissue- specific.

A further advantage is that the expression of the product coded for by a GOI in the aleurone layer of the endosperm gives minimal interference with the developing embryo and seedling. This is in direct contrast to constitutive promoters which give high levels of expression in the developing seedling and mature plant tissues which severely affect normal plant development.

The present invention is particularly useful for expressing GOI in the aleurone layer of developing grains - such as cereal seeds.

With regard to the present invention it is to be noted the EMBL database sequence listing *(ibid)* does not suggest that the Ltp2 gene promoter could be used to express a GOI in a stage- and tissue- specific manner. Also the database extract does not mention the importance of the myb gene segment or the myc gene segment.

It is also to be noted the paper titled "Molecular Strategies For Improving Pre-Harvest Sprouting Resistance In Cereals" *(ibid)* does not give any specific sequence listing information for the Ltp2 gene promoter. Also there is no explicit mention in this paper of using just the Ltp2 gene promoter to induce expression in just aleurone cells. Moreover, there is no mention in this paper of an Ltp2 - GOI conjugate being formed. Also there is no mention in this paper of the importance of the myb site or the myc site.

It is also to be noted that in the paper titled "Characterisation of Promoter Elements Of Aleurone Specific Genes From Barley" *(ibid)* there is no mention of an Ltp2 - GOI conjuagte stably integrated into genomic DNA of a cereal. Also there is no explicit disclosure of an <u>in vivo</u> expression system. Moreover, there is no full sequence listing in this paper for the Ltp2 gene promoter. Also there is no explicit mention in this paper of the importance of the myb site or the myc site of Ltp2 gene promoter for <u>in vivo</u> GOI expression.

In contrast to the work disclosed in PCT WO 90/01551, the Ltp2 gene promoter (which is not disclosed in PCT WO 90/01551) the Ltp2 gene promoter results in aleurone specific expression in developing grains.

In general, therefore, the present invention relates to a promoter for a Ltp2 gene encoding a 7 kDa nsLTP. *In situ* hybridization analysis demonstrates that the Ltp2 transcript is expressed exclusively in aleurone cells from the beginning of the differentiation stage and half-way into the maturation stage. Further commentary on the maturation stages is provided by Bosnes *et al.*, 1992.

The Ltp2 gene promoter may be inserted into a plasmid. For example, the Ltp2 BglII 0.84 kb fragment can be inserted into the *BamHI* site of Bluescript. A GOI, such as *GUS*, can then be inserted into this conjugate (construct). Furthermore, a *Sh*1 intron can then be inserted into the *Sma*I site of this conjugate.

Stable integration may be achieved by using the method of Shimamoto (1989). Another way is by bombardment of an embryonic suspension of cells (e.g. maize cells). Another way is by bombardment of immature embryos (e.g. barley embryos).

With the present invention, it can be shown by using particle bombardments that the -807 bp Ltp2 gene promoter fused to a beta-glucuronidase (*GUS*) reporter gene (which serves as a GOI) is active in the aleurone layer of developing barley seeds, giving 5% of the activity of the strong constitutive actin-promoter from rice. Also, in transgenic rice plants, the barley Ltp2-promoter directs strong expression of the *GUS*-reporter gene exclusively in the aleurone layer of developing seeds, suggesting the presence of conserved mechanisms for aleurone cell gene expression in the cereals.

In a preferred embodiment, the Ltp2 gene encodes a 7kDa barley seed nsLTP and has about 80% identity to the wheat 7kDa protein.

The transcript of the Ltp2 gene is detectable in the earliest morphologically distinguishable aleurone cells and accumulates during the differentiation stage to decline finally during seed maturation. It can also serve as a molecular marker for the differentiating aleurone cells as shown *in situ* hybridisation experiments where the spatial distribution of the transcript is to be examined.

In the present invention, a genomic clone was isolated using the cDNA insert of previously isolated cDNA clone pBz11E and characterised by DNA sequencing.

The sequence of the cDNA and isolated genomic clone was found to be identical in the overlapping region. It was found the Ltp2 gene does not contain any intron.

To prove that this is an active gene, the 5' region carried on a 845 bp DNA fragment delineated by two *Bgl* II restriction sites was fused to the *GUS* gene (following Jefferson 1987) and the construct was introduced into barley aleurone layers using micro projectile bombardment. Aleurone cells expressing *GUS* activity were detected proving that the gene promoter was indeed capable of driving the expression of the GOI in the relevant tissue.

By comparing the DNA sequence of this active promoter sequences several putative *cis*-acting elements with the potential of binding known transcriptional factors present in cereal aleurone layers were detected. They include the binding sites for transcriptional factors of the myb and myc class, namely TAACTG and CANNTG respectively. Our experiments showed that the myb and myc sites were important for good levels of expression.

Gel retardation experiments showed that the Ltp2 gene promoter has a myb site that is recognised by a MYB protein (e.g. from chicken).

In the present invention, mature fertile rice plants were regenerated from transformed cultured rice protoplasts. The developing seeds of these primary transformants were analysed for the expression of *GUS*. It was found that the barley seed Ltp2 gene promoter confers aleurone specific expression in transgenic rice plants. This is the first example of an aleurone specific promoter in developing seeds of a transgenic cereal.

The following were deposited in accordance with the Budapest Treaty at the recognised depositary The National Collections of Industrial and Marine Bacteria Limited (NCIMB) at 23 St Machar Drive, Aberdeen, Scotland, UK, AB2 1RY, on 22 November 1993:

(i) An *E. Coli* K12 bacterial stock containing the plasmid pLtp2pr - i.e. Bluescript containing the Ltp2 gene promoter (Deposit Number NCIMB 40598).

[To form pLtp2pr, the Ltp2 promoter of Figure 2b (see later) contained on a BglII fragment was inserted in the Bluescript KS vector into the BamHI site.]

(ii) An *E. Coli* K12 bacterial stock containing the plasmid pLtp2/GN - i.e. Bluescript containing a Ltp2 gene promoter - *GUS* conjugate (Deposit Number NCIMB 40599).

[To form pLtp2/GN, the *GUS*-reporter gene cassette (GN) contained on the SmaI-EcoRI fragment of the commercially available vector pBI101 (Clontech Inc.) was cloned directionally into the SmaI and EcoRI sites of pLtp2pr.]

(iii) An *E. Coli* K12 bacterial stock containing the plasmid pLtp2ΔBCIGN - i.e. Bluescript containing an Ltp2 gene promoter with a deletion spanning the myb and myc sites - *GUS* conjugate (Deposit Number NCIMB 40601).

[To form pLtp2ΔBCIGN, the Ltp2 promoter and the GN gene was inserted as described for pLtp2pr and pLtp2/GN except for the use of Bluescript SK and that the Ltp2 promoter was deleted in the myb-myc region (using a PCR strategy) as explained in the legend of Figure 7 (see later).]

(iv) An *E. Coli* K12 bacterial stock containing the plasmid pLtp2*Sh*1/GN - i.e. Bluescript containing an Ltp2 gene promoter-Sh1 intron-*GUS* conjugate (Deposit No. NCIMB 40600).

[To form pLtp2*sh*1/GN, the Ltp2 promoter and the GN gene was inserted as described for pLtp2pr and pLtp2/GN except for the use of Bluescript SK. The *Sh*1 intron from maize contained on a *Hinc*II restriction fragment was inserted into the SmaI site of this construct.]

Other embodiments and aspects of the present invention include: A transformed host having the capability of expressing a GOI in just the aleurone layer; A vector incorporating a conjugate as hereinbefore described or any part thereof; A plasmid comprising a conjugate as hereinbefore described or any part thereof; A cellular organism or cell line transformed with such a vector; A monocotylenedonous plant comprising any one of the same; A developping seed comprising any of the same; and A method of expressing any one of the same.

The present invention will now be described only by way of examples in which reference shall be made to the accompanying Figures in which:

Figure 1 is a nucleotide sequence of the Ltp2 gene;

Figure 2a is a nucleotide sequence of the Ltp2 gene promoter;
Figure 2b is a nucleotide sequence of the Ltp2 gene promoter with an additional 39 nucleotides for fusion to a *GUS* gene for transgenic rice and transient assay studies;

Figure 3 shows transverse sections from the mid-region of barley seeds (A-E) and steady state levels of the Ltp2 mRNA in different tissue fractions of developing barley endosperm;

Figure 4 shows the results for an *in situ* hybridization experiment;

Figure 5 is the result of a Southern blot experiment using DNA from transgenic rice plants;

Figure 6 shows the expression of a *GusA*-reporter gene driven by the Ltp2 gene promoter in the aleurone layer of developing transgenic rice seeds; and

Figure 7 shows the position of the myb and myc binding sites in the barley Ltp2 gene promoter.

A. METHODS

i. Plant material

Seeds of Barley (*Hordeum vulgare* cv. Bomi) were collected from plants grown in a phytotron as described before (Kvaale and Olsen, 1986). The plants were emasculated and pollinated by hand and isolated in order to ensure accurate determination of seed age.

ii. cDNA and genomic clones

The isolation and sequencing of the aleurone specific cDNA clone pBz11E (which is the same as Ltp2) was conducted as described by Jakobsen *et al.* (1989).

A barley, cv. Bomi genomic library was constructed by partial *Mbo*I digestion of total genomic DNA and subsequent ligation of the 10-20 kilo basepair (kb) size fraction with *Bam*HI digested lambda EMBL3 DNA (Clontech Labs, Palo Alto, Ca, USA). Out of a total of 2 x 10^6 plaques screened, using the Bz11E cDNA insert as a template for probe synthesis with a random labelling kit (Boehringer-Mannheim), four positive clones (gHv29-101, gHv38-201, gHv53-201 and gHv59-101) were identified after repeated rounds of plaque hybridization. DNA purified from these clones were restricted with several enzymes and characterized by Southern blot analysis.

The restriction maps of the four clones showed extensive overlap. One clone, gHv53-201, containing an insert of around 12 kb, was chosen for further analysis. A 6 kb *Pst*I fragment contained within the insert that hybridized to the cDNA probe was subcloned into Bluescript (Stratagene) giving the subclone BL53Ps17. A *Nhe*I restriction fragment of 0.7 kb covering the coding region of the Ltp2 gene was cloned into the *Xba*I site of M13mp18 and sequenced using the Sequenase protocol (USB) after isolation of ssDNA template using PCR amplification and magnetic beads (Dynabeads M280- Streptavidin, Dynal).

In order to characterize the 5' and 3' sequences of the Ltp2 gene, the following DNA fragments were generated by PCR amplification:

i) a 1.2 kb fragment covering the 5' end from a vector primer (KS) to the PLT11 primer located within the 5'end of the cDNA; and

ii) a 0.3 kb PCR product generated by amplification directed by the primers LTP13 and PLT15, of which the latter is based upon sequence information from the cDNA clone Bz14A, which is overlapping and identical with the Bz11E cDNA but contains some additional 30 base pairs after the polyadenylation site indicated at position 490 in Figure 1.

The sequences are:

KS:	5'	CGAGGTCGAC	GGTATCG		3'
PLT11:	5'	TACGG**T**GATC	TACTCGGCTA		3'
LTP13:	5'	ACGAAGCCGA	GCGGCGAGT		3'
PLT15:	5'	GGACTAAAAA	AAAAGTTGCA	ACACAAATTT C	3'.

The PLT11 sequence contains one base substitution (shown in bold and underlined) creating a *Bgl*II restriction site.

The 1.2 kb PCR product containing the 5' end was restricted with *Bgl*II which gave a 0.84 kb fragment with *Bam*HI compatible sticky ends that was subsequently cloned into the *Bam*HI site of pBluescript.

The 0.3 kb PCR product of the 3' end was treated with T4 DNA polymerase (Sambrook *et al.*, 1989) and subsequently cloned into the *Sma*I site of M13mp18.

The sequences of the PCR products were determined as described above.

iii. N rthern analyses

Total RNA was extracted from barley seed tissues of 10 DAP and older plant material essentially as described by Logemann *et al.* (1987), except that LiCl precipitation was used in place of ethanol precipitation. The RNA was denatured using formaldehyde and separated on 1.2% agarose gels as described by Selden (1987) and blotted onto GeneScreen (NEN) membranes using a Stratagene posiblotter apparatus according to supplier's instructions.

Hybridization was according to GeneScreen instruction manual (NEN) using radioactively labelled DNA strands complementary to the pBz11E cDNA insert generated with a random primed DNA labeling kit (Boehringer Mannheim).

iv. *In situ* hybridization

For *in vitro* transcription of antisense RNA, the plasmid pBz11E (Jakobsen *et al.*, 1989) was linearized with *Pst*I and transcribed with T7 RNA polymerase by using MAXIscript (Ambion) and [5,6-3H]-Uridine 5'-triphosphate (40-60 Ci mmol-1) (Amersham International) according to the specifications of the suppliers. The probe was hydrolyzed to fragments of about 100 bp as described by Somssich *et al.* (1988). Seed tissues were fixed in 1% glutaraldehyde, 100 mM sodium phosphate (pH 7.0) for 2 hours and embedded in Histoplast (Histolab, Göteborg, Sweden).

Sections of 10 μm were pretreated with pronase (Calbiochem) as described by (Schmelzer *et al.*, 1988) and hybridized with 25 ml of hybridization mix (200 ng probe ml-1, 50% formamide, 10% (w/v) dextran sulphate, 0.3 M NaCl, 10 mM Tris-HCl, 1 mM EDTA (pH 7), 0.02% polyvinyl- pyrrolidone, 0.2% Ficoll, 0.02% bovine serum albumin) for 15 hours at 50 °C.

Posthybridization was carried out according to Somssich *et al.* (1988) and autoradiography was done as described by Schmelzer *et al.* (1988), except that sections were exposed for 10 weeks.

v. Constructs for transient expression analysis

For the microprojectile bombardment experiments, the following constructs were used:

CONTROL A: pAct1f-*GUS* containing the rice *Actin 1* promoter fused to the *uidA* reporter gene encoding the *GUS* enzyme (McElroy *et al.*, 1990);

CONTROL B: pRT101-ex/s-int/s-LUC containing the *35S* CaMV promoter-*Sh1* first exon/intron fused to the firefly luciferase gene (Maas *et al.*, 1991); and

CONTROL C: pRT101C1 containing the *C1* cDNA downstream of the *35S* CaMV promoter (Paz-Ares *et al.*, 1987);

CONTROL D: pMF6Lc(R) containing the *Lc* cDNA corresponding to one *R* gene allele coupled to the *35S* CaMV promoter-*Adh1* intron (Ludwig *et al.*, 1989).

For the transient expression studies in barley aleurone the first intron of the maize *Sh1* gene carried on a 1.1 kb *Hinc*II fragment (Maas *et al.*, 1991) was inserted into the *Sma*I site of the promoter-reporter gene constructs according to the present invention. The Ltp2 gene promoter is contained on the 0.84 kb *Bgl*II fragment (sequence is presented in Figure 2) and was inserted into the *Bam*HI site of pBluescript. Thereafter the structural uidA gene encoding the beta-glucuronidase (*Gus*) enzyme was fused to the Ltp2 gene promoter.

The following conjugates according to the present invention were studied:

(i) Ltp2/GN: A Ltp2 gene promoter - *GUS* conjugate (same as conjugate in pLtp2/GN - see earlier);

(ii) Ltp2*Sh*1/GN: A Ltp2 gene promoter - Sh1 intron - *GUS* conjugate (same as conjugate in pLtp2*Sh*1/GN - see earlier).

Isolated plasmid DNA was used in the bombardment studies. The same conditions were used for the control conjugates and for the conjugates of the present invention.

For transient assay studies with rice protoplasts, the following conjugates according to the present invention were studied:

(i) Ltp2/GN: As above; and

(iii) Ltp2ΔBCIGN: A Ltp2 gene promoter {with a deletion spanning the myb and myc sites} - *GUS* conjugate (same as conjugate in pLtp2ΔBCIGN - see earlier).

vi. **Transformation of barley aleurone layers by particle bombardment**

Barley seeds were harvested at 25 DAP, surface sterilized in 1% sodium hypochlorite for 5 min and then washed 4 times in sterile distilled water. The maternal tissues were removed to expose the aleurone layer and the seed was then divided into two, longitudinally along the crease. The pieces of tissue were then placed, endosperm down, onto MS (Murashige & Skoog 1962) media with 10 g/l sucrose solidified with 10 g/l agar in plastic petri dishes (in two rows of 4 endosperm halves per dish).

Single bombardments were performed in a DuPont PDS 1000 device, with M-17 tungsten pellets (approx. 1 μm in diameter) coated with DNA as described by Gordon-Kamm *et al.* (1990) and using a 100 mm mesh 2 cm below the stopping plate. Equal amounts (25 μg per preparation) of the *GUS* (promoter-reporter gene) and LUC (internal standard) plasmids were mixed before adding the microprojectiles. One tenth of this amount, 2.5 μg, was used for the *Lc* and *C1* cDNA constructs. Bombarded tissue was incubated at 24°C for 3-4 days before extraction and measurement of *GUS* and LUC activities. Anthocyanin pigmentation could be observed in the bombarded aleurones directly without further treatment.
Histochemical staining for *GUS* expression was performed with X-Gluc (5-bromo,4-chloro,3-indolyl,ß-D,Glucuronic acid) as described by Jefferson (1987) at 37°C for 2 days. Extraction of cellular proteins for quantitative analysis was performed by grinding 4-8 half seeds in a mortar and pestle with 0.5 ml of extraction buffer (50 mM Na-phosphate pH, 1 mM DTT, pH 7.0).

After grinding, a further 0.5 ml was added and two 400 μl aliquots were taken. To one of these, 100 μl of 5 x Luciferase cell lysis buffer (Promega) was added and the sample vortexed before clearing by centrifugation at 10,000 rpm. A 20 μl aliquot was then measured for LUC activity in a scintillation counter (Tri-Carb 4000), using the luciferase assay system of Promega (E1500). To the other 400 μl aliquot, 100 μl of 5x lysis buffer (500 mM Na phosphate pH 7.0, 50 mM EDTA, 10 mM DTT, 0.5% Sarcosyl, 0.5% Triton X-100) was added, the mixture vortexed and cleared as above and assayed for *GUS* activity using 4-methylumbelliferone, ß-D,glucuronide as described by Jefferson (1987) modified to include 5% methanol in the reaction mixture (Kosugi *et al.*, 1990).

Production of 4-methylumbelliferone (MU) was measured after 1 and 4 h using a TKO 1000 Mini-Fluorimeter (Hoefer Scientific Instruments). In the analysis of promoter activities, the *GUS* readings (MU produced per hr) were standardized by division with the LUC value (photons produced over 30 s, beginning 60 s after mixing) from the same extract.

vii. Transient assay of rice protoplasts

In this experiment, the same type of protoplasts as used for stable transformation of rice plants was transiently transformed with constructs (i) and (iii) (see above) and then assayed for *GUS* activity.

viii. Rice transformation

Southern blot analysis of transgenic rice plants

Total genomic DNA was isolated from mature leaves, digested with *Xba* I and then transferred to a nylon membrane (Amersham). The coding region of the *GUS* gene was labelled and amplified with digoxigenin 11-dUTP by polymerase chain reaction and used for probing the Ltp2 - *GUS* gene. Hybridization and chemiluminesence signal detection were performed according to manufacturers specifications (Boeringen Mannheim).

B. RESULTS WITH REFERENCE TO THE FIGURES

i. **Figure 1** is a nucleotide sequence of the Ltp2 gene. A transcription start site has been assigned as +1. The TATA consensus sequence is boxed. Consensus myb and myc binding sites and the *SphI* element (Hattori *et al.*, 1992) found in the *C1* promoter sequence are shown in bold italics.

In the ORF (open reading frame), the nucleotides are shown in bold letters, starting with the first ATG codon and ending with the TAG stop codon. The single base substitution introduced at position +41 (A>T) creates a *BglII* restriction site which delimits the 3' end of the fragment covering the Ltp2 gene promoter. The positions of the 5' end and polyadenylation site of the corresponding cDNA, Bz11E (Jakobsen *et al.*, 1989), are shown by arrows. Two putative polyadenylation signals are underlined.

ii. **Figure 2a** is a nucleotide sequence for the Ltp2 gene promoter. Figure 2b is a nucleotide sequence for the Ltp2 gene promoter with an additional number of nucleotides for fusion to a *GUS* gene.

iii. **Figure 3** shows transverse sections from the mid-region of barley seeds (A-E) and steady state levels of the Ltp2 mRNA in different tissue fractions of developing barley endosperm (F).

Figure 3 can be analysed as follows:

> **(A)**: Ten DAP (days after pollination) endosperm isolated from the surrounding maternal tissues by manual extrusion. For maternal tissues, see (C). The extruded endosperm consists of the central starchy endosperm cells, a group of modified aleurone cells over the crease area (arrow) and one layer of highly vacuolated peripheral aleurone cells (arrowhead).
>
> **(B)**: Enlargement showing vacuolated peripheral aleurone cells (AC) and starchy endosperm cells (SE) in area of (A) marked with arrowhead.

(C): Pericarp of 10 DAP seed after extrusion of the endosperm with the nucellus epidermal layer (NE) facing the endosperm cavity, which contained the endosperm in (A) before extrusion.

(D): Extruded 15 DAP endosperm with central starchy endosperm cells and modified aleurone cells (arrow), but without peripheral aleurone cells.

(E): 15 DAP pericarp with adhering aleurone layer after extrusion of the endosperm (in D).

(F): Northern blot showing the steady state level of Ltp2 mRNA in the extruded endosperm fraction (e) and the pericarp fraction (p) in the interval from 10 to 13 DAP. For this blot, 10 μg of total RNA was loaded in each lane. The gel was blotted and hybridized with randomly primed Ltp2 cDNA.

iv. **Figure 4** shows the results for an *in situ* hybridization of ^{3}H-labelled Ltp2 antisense probe to transverse sections of barley endosperm (A and B) and transient gene expression analysis of different promoter-reporter gene constructs in developing barley aleurone layers after particle bombardment (C, D and E). Figure 4 can be analysed as follows:

(A): Dark field microphotograph of 13 DAP endosperm showing hybridization of the Ltp2 probe to the peripheral aleurone cells (AL) ventrally and laterally, but not to aleurone cells on the dorsal side of the grain (DS), nor to the modified aleurone cells over the crease area (MA).

(B): Magnification of peripheral endosperm (frame in A) showing gradient of *in situ* hybridization signal towards the dorsal side of the seed containing undifferentiated aleurone cells.

(C): Colourless barley aleurone layer co-bombarded with the *35S-C1* and *35S-Lc* cDNA constructs. Single aleurone cells synthesizing anthocyanin pigment appear as red spots.

(D): Exposed aleurone layer of 25 DAP barley seeds bombarded with the Ltp2/*Sh1* int/*GUS* construct. The transfected seed was stained for detection of *GUS* activity.

(E): Exposed aleurone layer of barley seed of the same stage bombarded with *pAct1f-GUS* construct and histochemically stained as in (D).

(V): Ventral crease area.

v. **Figure 5** is the result of a Southern blot experiment of DNA from transgenic rice plants harbouring the Ltp2-*GUS* construct. Figure 5 can be analysed as follows:

Lane P: plasmid Ltp2-*GUS*.

Lane C: untransformed control plants.

Lane 1: transgenic line 3-15.

Lane 2: transgenic line 4-13.

Lane 3: transgenic line 2-6.

Lane 4: transgenic line 4-6.

vi. **Figure 6** shows the expression of a *GUS*-reporter gene driven by the Ltp2-wildtype promoter in the aleurone layer of developing transgenic rice seeds. Figure 6 can be analysed as follows:

(A): Longitudinal section of 20 DAP seed showing *GUS* staining exclusively in the aleurone layer (AL), but not in the embryo, starchy endosperm (SE) or in the maternal tissue (M).

(B): Transverse section from the mid-region of 20 DAP seed.

(C): Enlargement of dorsal side of seed shown in (A).

(D): Non-transgenic control seed, same age as in (A).

(E): A 5 day-old seedling transformed with the Ltp2 - *GUS* gene.

(F): A 5 day-old seedling transformed with the CaMV35S - *GUS* gene. (Terada and Shimamoto 1990). Arrows indicate regions of *GUS* expression. Bars in (A,B and D) are 10 mm and in (C) 2.5 mm.

vii. **Figure 7** shows the position of the myb and myc sites in the barley Ltp2 gene promoter. The distance from the 3' end of the myc site to the TATA box is given in nucleotides. The following nucleotides from and between the myb and myc sites were deleted to form the conjugate containing the deletion in the Ltp2 gene promoter gene:

CAACTACCATCGGCGAACGACCCAGC.

C. CONCLUSIONS

1. *The barley Ltp2 gene encodes a protein homologous to the 7 kDa wheat lipid transfer protein*

Using the Bz11E cDNA (Jakobsen *et al.*, 1989) as a probe, the corresponding barley cv. Bomi genomic clone was isolated. The sequences of the genomic clone and that of the Bz11E cDNA are identical in overlapping regions and no intervening sequences were detected (Figure 1) accordingly this gene is Ltp2. The ATG codon initiating the longest open reading frame (ORF) in the Ltp2 sequence is located 64 bp downstream of the putative transcriptional start site at nucleotide number 1 (Figure 1). The ORF contains eight potential translation start codons between nucleotides 64 and 127. Two polyadenylation signals, which conform to the plant consensus sequence (Joshi, 1987) are found in the 3' end of the genomic sequence. In the Bz11E cDNA the polyA tail extends after the G at position 491 (Figure 1 and Figure 2).

2. *The Ltp2 transcript can be a molecular marker for peripheral aleurone cell differentiation*

In the developing seed at approximately 8 days after pollination (DAP), aleurone cell differentiation is initiated over the ventral crease area resulting in the formation of the modified aleurone cells (Figure 3A and Bosnes *et al.*, 1992). Shortly after, at 9 DAP, the second type of aleurone cells, characterized by their extensive vacuolation (Figure 3B), appears in the peripheral endosperm close to the crease area, spreading first laterally and then to the dorsal side of the seed (see Figure 3A). At this stage, when whole de-embryonated seeds are squeezed, the extruded endosperm consists of the starchy endosperm, the peripheral and the modified aleurone cells (Figure 3 A-C). This is in contrast to later developmental stages, where the extruded endosperm consists only of the starchy endosperm and the modified aleurone cells (Figure 3D). The reason for this is that the cells of the aleurone layer adhere to the maternal pericarp (Figure 3E). Aleurone cell formation is completed at 21 DAP, when cell division stops (Kvaale and Olsen, 1986). Using the Ltp2 probe on Northern blots with total RNA, the signal obtained gradually becomes stronger in the pericarp, compared to the extruded endosperm, confirming the relocation of the aleurone cells from the endosperm fraction to the pericarp fraction in the interval between 10 and 13 DAP (Figure 3F).

From the experimental results presented in Figure 3 it is concluded that the Ltp2 transcript is a potential marker for aleurone cell differentiation. To corroborate the usefulness of the Ltp2 transcript as a molecular marker for aleurone cell differentiation, *in situ* analysis was carried out on transverse sections of 13 DAP seeds. The rationale for using seeds from this stage was the earlier observed gradual differentiation of the peripheral aleurone cells, starting near the crease area and spreading to the dorsal side (Bosnes *et al.*, 1992).

Using ^{3}H-labelled antisense transcript as probe, a positive signal is clearly visible in the peripheral aleurone cells in the ventral part adjacent to the crease area as well as laterally up towards the dorsal side of the grain (Figure 4A). However, no signal is present in the dorsal region of the seed, nor over the modified aleurone cells.

Focusing on the most dorsal aleurone cells showing a positive signal in the *in situ* analysis (Figure 4B), the morphology of these cells corresponds to that of the highly vacuolated peripheral aleurone cells in 10 DAP endosperm (Figure 3B).

The Ltp2 transcript therefore represents a highly tissue specific molecular marker for aleurone cell differentiation.

3. *The Ltp2 gene promoter is transiently expressed in developing barley aleurone cells after particle bombardment*

The Ltp2 gene promoter contained on a 842 bp *BglII* restriction fragment (from nt -807 to nt +35 in Fig.1) was fused to the *GUS*-reporter gene and introduced into the exposed aleurone layers of 25 DAP whole barley seeds by the biolistic method. In the first set of experiments, Ltp2 gene promoter activity was assayed visually after histochemical staining with X-Gluc. Due to the large variation between individual experiments with the biolistic method, plasmid DNA containing the *Lc* and *C1* cDNAs from maize under the control of the 35S CaMV promoter was co-bombarded with the Ltp2 construct to monitor shooting efficacy. In combination, but not individually, the latter two cDNAs give high numbers of red anthocyanin spots in the barley aleurone cells without any treatment after 1 to 2 days of incubation of the seeds on solid nutrient medium (Figure 4C). Compared to the number of red spots, the Ltp2-*GUS* construct consistently gave very few spots after histochemical staining in co-bombardment experiments.

Based on previous reports that insertion of introns in promoter construct enhance the level of transient expression (Maas *et al.*, 1991) without interfering with the tissue specificity of the promoters, the intron from the maize *Shrunken-1* gene was inserted into the Ltp2-*GUS* construct after the promoter. Using this construct the number of spots in immature aleurone layers increased (Figure 5D). Still, however, compared to aleurone layers bombarded with the *pAct1f-GUS* construct (McElroy *et al.*, 1990), which contains the promoter of the constitutively expressed *Actin1* gene from rice (Figure 4D), both the number and the size of the spots obtained with the Ltp2-*GUS* construct is dramatically smaller (Figure 4E).

In order to quantify Ltp2 gene promoter activity in particle bombardment experiments, another control plasmid containing the *LUC* gene under the control of the 35S-promoter was co-bombarded with the Ltp2-*GUS* constructs. In this way, after particle bombardment and incubation on tissue culture medium, protein was extracted from the seeds in a buffer that allowed measurement of both LUC and *GUS* activity (for details, see Materials and Methods section). In such experiments, calculating *GUS* expression standardized on the base of the LUC-activity, the Ltp2-*GUS* activity was not significantly higher than background, corresponding approximately to 1.5% of the Actin1f promoter activity in parallel experiments.

For the Ltp2-*Sh1* intron-*GUS* construct, however, the activity was significantly higher than background, corresponding to 5% of that of the *Actin1* promoter. Blue spots from the activity of the Ltp2-promoter were never observed in other tissues than the aleurone layer of developing seeds. From these experiments it is concluded that the -807 bp promoter of the Ltp2 gene is capable of directing transient gene expression in a fashion similar to that of the endogenous Ltp2 gene, i.e., in the cells of the aleurone layer of immature barley seeds.

4. The Ltp2 gene promoter directs aleurone specific expression of the GUS-reporter gene in transgenic rice seeds

The gene was transformed into rice by electroporation of embryogenetic protoplasts following the teachings of Shimamoto et al. 1989.

Four fertile transgenic rice plants were obtained and integration of the Ltp2-*GUS* gene was examined by Southern blot analysis. The results demonstrated that a 2.9 b fragment containing the Ltp2-*GUS* gene is integrated in all the transgenic lines. Histochemical *GUS* analysis was carried out with developing rice seeds of 20 DAP and 5 day old seedings derived from transgenic seeds (Figure 6). In developing seeds the *GUS* expression is strictly limited to the aleurone layer, with no staining observed in the maternal tissues, starchy endosperm or in the embryo of the transgenic seeds (Figure 6 A-C), nor in untransformed control seeds (Figure 6 D). No *GUS* staining was observed in leaves or roots of seedlings transformed with the Ltp2 - *GUS* gene (Figure 6 E).

In contrast, seedlings transformed with the CaMV35S - *GUS* gene *GUS* expression is detected in the coleptile, shoots and roots (see Figure 6 F; Terada and Shimamoto 1990).

These results clearly demonstrate the aleurone-specific expression of the Ltp2 - *GUS* gene in transgenic rice plants.

5. The Ltp2 gene promoter contains sequence elements implicated in the transcriptional control of cereal endosperm specific genes

The studies with the deletion spanning the myb and myc sites in the Ltp2 gene promoter showed that levels of expression were about 10% of that of the wild-type gene promoter. These studies indicated that both the myb and myc sites are important for expression.

In addition, the Ltp2 gene promoter may even contain another sequence element that has been implicated in regulation of gene expression in maize aleurone cells, namely the octanucleotide CATGCATG (Figure 1). This sequence, previously referred to as the *Sph*I element, has been shown to mediate the transcriptional activation of maize *C1* by interaction with VP1 (Hattori *et al.*, 1992). As in the maize *C1* promoter (Paz-Ares *et al.*, 1987), the putative *Sph*I element of the barley Ltp2 gene promoter is located between the TATA-box and the myb binding site.

In addition, the Ltp2 gene promoter may contain two further sites that could play an important role in transcription. The first site is an "AL" site and has the sequence

CATGGAAA

This AL sequence ends at position -366 in the sequence shown in Figure 1.

The second site is a "DS" site that has a high degree of similarity or identity with the binding site for 5' transcriptional factors from other eucaryotic organisms. This DS site, which a dyad-symmetry, has the sequence

TCGTCACCGACGA

This DS sequence ends at position -121 in the sequence shown in Figure 1.

D. DISCUSSION

The above examples of the present invention concern the barley gene Ltp2, which encodes an aleurone specific 7 kDa nsLTP.

The identification of the Ltp2 protein as a nsLTP is based on the high identity (78%) between the predicted Ltp2 amino acid sequence and the 7 kDa protein isolated from wheat seeds using the *in vitro* lipid transfer assay (Monnet, 1990). The high degree of sequence identity between the two barley aleurone Ltp gene products and the homologous proteins and transcripts from wheat seeds strongly suggests that the aleurone layer of these two cereals contain two related classes of nsLTPs with molecular masses of 10 and 7 kDa, respectively.

While the sequence identity is more than 70% within the two classes, it is only around 20% between them. However, several conserved features are apparent in the cereal seed nsLtps, including similar N-terminal signal peptides, an internal stretch of 20 amino acids with 60% similarity, and 8 cysteine residues that are believed to be important for the activity of plant Ltps (Tchang *et al.*, 1988). Studies also showed that the Ltp2 gene lacks an intron. Hybridization experiments using Ltp2 probes to barley genomic Southern blots indicate that the barley haploid genome contains only one copy of each gene (Jakobsen *et al.*, 1989; Skriver *et al.*, 1992).

According to a suggestion by Sterk *et al.* (1991) plant nsLTPs may be involved in the extracellular transport of cutin or other lipid monomers from the endoplasmic reticulum to the site of synthesis of extracellular matrix components, such as the cuticle. Therefore, one possible role for the aleurone specific nsLTPs in barley and wheat could be in the formation of the earlier described amorphous layer on the outside of the aleurone cells in wheat seeds (Evers and Reed, 1988). The function of this layer is unknown, but it may be involved in the regulation of the osmotic pressure in the endosperm during seed development and germination. If this holds true, the absence of the Ltp2 transcript in the modified aleurone cells in the ventral crease area is functionally significant, since an impermeable layer on the outside of these cells would prevent the influx of soluble synthates from the vegetative plant parts.

Of the nine cDNAs isolated in the differential screening experiment design to identify clones representing transcripts differentially expressed in the aleurone layer of developing barley seeds, Ltp2 hybridizes to transcripts present exclusively in the aleurone layer. Thus, the Ltp2 gene represents a suitable gene for the search for promoter sequences responsible for the control of gene transcription in the aleurone layer.

Due to the lack of a routine protocol for stable barley transformation, demonstration of Ltp-promoter specificity in barley has to rely on transient assays using the particle bombardment method. Using this method, it was demonstrated that the -807 bp Ltp2 gene promoter carried on the *Bgl*II restriction fragment is capable of driving the expression of the *GUS* reporter gene in immature barley aleurone layers. From this it is concluded that the promoter fragment carries sequences that are responsible for barley aleurone specific gene transcription.

The Ltp2 gene promoter can be weaker than constitutive cereal promoters like that of the *Actin1f* gene - even after the introduction of the *Sh1*-intron (see Maas *et al.* (1991) and their work on tobacco protoplasts) into the Ltp2-*GUS* construct which increases the expression levels by around three-fold. However, this lower expression does not result in any damage to the developing seedling - unlike the constitutive cereal promoters. Moreover, and again unlike the constitutive cereal promoters, the Ltp2 gene promoter directs desirable tissue and stage specifc expression.

As demonstrated by the histochemical assays shown in Figure 6, the Ltp2 *Bgl*II promoter fragment shows the same aleurone specific expression in developing rice seeds as in barley.

Thus, the conclusion from the transient assays in barley that this promoter fragment contains sequences responsible for aleurone specific gene transcription is confirmed. Furthermore, the data from rice provide support to the view that the molecular mechanisms underlying aleurone specific gene transcription in developing seeds are conserved among the cereal species.

E. SUMMATION

The Examples describe the isolation of the promoter for the barley gene Ltp2, which encodes a novel class of cereal 7 kDa nsLTPs. The gene was isolated by the use of a cDNA from a differential screening experiment in which the positive probe was constructed from aleurone cell poly (A) rich RNA, and the negative probe from the starchy endosperm of immature seeds.

In situ hybridization analysis demonstrates that the Ltp2 transcript is expressed exclusively in the aleurone layer from the beginning of the differentiation stage and half way into the maturation stage. Similar to previously identified 10 kDa plant nsLTPs, the Ltp2 protein contains the eight conserved cysteine residues.

The results indicate that the Ltp2 protein is involved in the synthesis of a lipid layer covering the outside of the cereal aleurone cells.

Using particle bombardments it was shown that the -807 bp Ltp2 gene promoter fused to the *GUS*-reporter gene is active in the aleurone layer of developing barley seeds, giving 5% of the activity of the strong constitutive actin1f-promoter from rice. Transformed into rice, the barley Ltp2-promoter directs strong expression of the *GUS*-reporter gene exclusively in the aleurone layer of developing rice seeds. Analysis of the Ltp2 gene promoter reveals the presence of sequence motives implicated in endosperm specific gene expression in maize, i.e. the myb and myc protein binding sites. In short, the Ltp2 gene promoter represents a valuable tool for the expression of GOIs in the aleurone layers of cereal seeds.

Other modifications of the present invention will be apparent to those skilled in the art without departing from the scope of the invention.

INDICATIONS RELATING TO A DEPOSITED MICROORGANISM

(PCT Rule 13*bis*)

A. The indications made below relate to the microorganism referred to in the description on page 11, line 6

B. IDENTIFICATION OF DEPOSIT — Further deposits are identified on an additional sheet ☐

Name of depositary institution

The National Collections of Industrial and Marine Bacteria Limited (NCIMB)

Address of depositary institution *(including postal code and country)*

23 St. Machar Drive
Aberdeen
Scotland
AB2 1RY
United Kingdom

Date of deposit	Accession Number
22 November 1993	NCIMB 40598

C. ADDITIONAL INDICATIONS *(leave blank if not applicable)* — This information is continued on an additional sheet ☐

In respect of those designations in which a European patent is sought, and any other designated state having equivalent legislation, a sample of the deposited microorganism will be made available until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or withdrawn or is deemed to be withdrawn, only by the issue of such a sample to an expert nominated by the person requesting the sample. (Rule 28(4) EPC).

D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE *(if the indications are not for all designated States)*

E. SEPARATE FURNISHING OF INDICATIONS *(leave blank if not applicable)*

The indications listed below will be submitted to the International Bureau later *(specify the general nature of the indications e.g., "Accession Number of Deposit")*

For receiving Office use only	For International Bureau use only

CLAIMS

1. An in vivo expression system comprising a conjugate comprising a GOI and a Ltp2 gene promoter comprising the sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof; wherein the conjugate is integrated, preferably stably integrated, within a monocotyledon's genomic DNA.

2. A transgenic cereal comprising a conjugate comprising a GOI and a Ltp2 gene promoter as defined in claim 1 wherein the conjugate is integrated, preferably stably integrated, within a cereal's genomic DNA.

3. The in vivo expression in the aleurone cells of a monocotyledon of a conjugate comprising a GOI and a Ltp2 gene promoter as defined in claim 1; wherein the conjugate is integrated, preferably stably integrated, within the monocotyledon's genomic DNA.

4. A method of enhancing in vivo expression of a GOI in just the aleurone cells of a monocotyledon which comprises stably inserting into the genome of those cells a DNA conjugate comprising a Ltp2 gene promoter as defined in claim 1 and a GOI; wherein in the formation of the conjugate the Ltp2 gene promoter is ligated to the GOI in such a manner that each of the myb site and the myc site in the Ltp2 gene promoter is maintained substantially intact.

5. Use of a myb site and a myc site in a Ltp2 gene promoter to enhance in vivo expression of a GOI in just in the aleurone cells of a monocotyledon wherein the Ltp2 gene promoter and the GOI are integrated into the genome of the monocotyledon.

6. A conjugate comprising a GOI and a Ltp2 gene promoter comprising the sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

7. The invention of any one of claims 1 to 6 wherein the promoter is a barley aleurone specific pr moter.

8. The invention of claim 7 wherein the promoter is for a 7 kDa lipid transfer protein.

9. The invention of any one of claims 1 to 8 wherein the promoter is used for expression of a GOI in a cereal seed.

10. The invention of any one of claims 1 to 9 wherein the promoter is used for expression of a GOI in a transgenic cereal seed.

11. The invention of any one of claims 1 to 10 wherein the cereal seed is any one of a rice, maize, wheat, or barley seed, preferably maize.

12. The invention of any one of claims 1 to 11 wherein the promoter is the promoter for Ltp2 of *Hordeum vulgare*.

13. The invention according to any one of the preceding claims wherein the conjugate further comprises at least one additional sequence to increase expression of a GOI or the GOI.

14. The invention according to any one of the preceding claims wherein the conjugate is stably integrated within the genome of a developing grain.

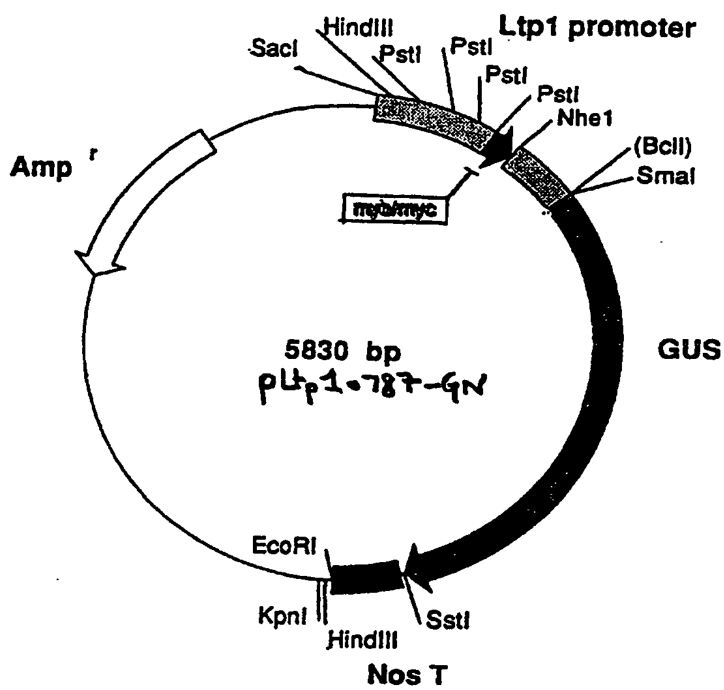
(54) Title: PROMOTER FROM A LIPID TRANSFER PROTEIN GENE

(57) Abstract

An expression system for at least the aleurone cells of a developing caryopsis or for at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem) is described. The expression system comprises a gene promoter fused to a GOI (gene of interest). In a preferred embodiment the expression system comprises the GOI fused to a modified Ltp1 gene promoter.



PROMOTER FROM A LIPID TRANSFER PROTEIN GENE

The present invention relates to a promoter and to a construct comprising the same.

In particular the present invention relates to the use of a promoter for the expression of a gene of interest (GOI) in a specific tissue or tissues of a plant.

More in particular the present invention relates to a modified promoter for a lipid transfer protein (Ltp) gene known as the Ltp1 gene. The present invention also relates to the application of this modified Ltp1 gene promoter to express a GOI in a specific tissue or specific tissues of a plant. For example, expression can be in either the aleurone layer or the scutellar epithelial layer of a monocotyledon, especially a transgenic cereal caryopsis (or grain), more especially a developing transgenic cereal caryopsis (or grain). Particular examples include expression in the scutellar epithelial tissue or vascular tissue of a transgenic rice plant, in particular in the vascular bundles and tip of emerging shoots and roots, leaf veins and vascular bundles of stems.

A diagrammatic illustration of a developing caryopsis (or grain) is presented in Figure 1, which is discussed in detail later. In short, a typical developing caryopsis (or grain) comprises an endosperm component and an embryo component. The endosperm, which is the site of deposition of different storage products such as starch and proteins, supports the growth of the emerging seedling during a short period of time after germination. The embryo gives rise to the vegetative plant. These components and aspects are further discussed in Bosnes *et al.* 1992 and Olsen *et al.* 1992.

The embryo component can be divided into a scutellum and an embryo axis. The scutellum can be sub-divided into an epithelial layer, which is usually one cell thick, and an inner body of parenchyma cells. Likewise, the embryo axis can be sub-divided into a root component and a shoot component.

The endosperm component of mature grains can be divided into a peripheral layer of living aleurone cells surrounding a central mass of non-living starchy endosperm cells. The aleurone layer in barley is three cells thick. During caryopsis germination, the cells of the aleurone layer produce amyolytic and proteolytic enzymes that degrade the storage compounds into metabolites that are taken up and are used by the growing embryo.

Two aspects of aleurone cell biology that have been intensively studied are the genetics of anthocyanin pigmentation of aleurone cells in maize (McClintock, 1987) and the hormonal regulation of gene transcription in the aleurone layer of germinating barley caryopsis (Fincher, 1989). Using transposon tagging, several structural and regulatory genes in the anthocyanin synthesis pathway have been isolated and characterized (Paz-Ares *et al.*, 1987; Dellaporta *et al.*, 1988). In barley, α-amylase and β-glucanase genes that are expressed both in the aleurone layer and embryos of mature germinating caryopsis have been identified (Karrer *et al.*, 1991; Slakeski and Fincher, 1992). In addition, two other cDNAs representing transcripts that are differentially expressed in the aleurone layers of developing barley grains have been isolated. These are CHI26 (Lea *et al.*,1991) and pZE40 (Smith *et al.*, 1992).

None of these references discloses expression of those gene products in specific cell types of developing grains of transgenic cereal plants or in the scutellar epithelial tissue or vascular tissue of a germinating rice seedling or a developing rice grain or rice plant.

In the life of a developing caryopsis (or grain), the embryo component of a dried caryopsis will imbibe water. The presence of water triggers the production of the hormone gibberellic acid in the embryo. In barley and other grass caryopsis, the embryo releases the gibberillic acid which in turn causes expression of a number of genes in the aleurone layer of the endosperm resulting in the production of a number of enzymes such as α-amylases, proteases and β-glucanases. Similar enzymes are also produced by expression of genes in the epithelial layer.

These degradative enzymes digest certain components of the developing caryopsis (or grain) to form sugars and amino acids.

For example, the α-amylases digest the starch store in the starchy endosperm, whereas the proteases digest the storage proteins and the β-glucanases digest the cell walls. The resultant sugars and amino acids cross the epithelial layer and trigger growth of the shoot and root of the embryo axis - i.e. start the germination process.

In some cases it is desirable to transform seeds, grains, caryopsis and plants by introducing genes which, as a result of their expression, yield new or improved properties to the resulting transformed seeds, grains, caryopsis or plants. For example, it may be desirable to alter the expression levels of a natural structural gene which may be under- or over- expressed. It may even be desirable to reduce or eliminate a disease which harms or destroys the seed, grain, caryopsis or the plant.

It may even be desirable to make the seed, grain, caryopsis or the plant resistant to herbicides. It may even be desirable to prevent or to reduce the extent of pre-harvest sprouting.

It may even be desirable for the seed, grain, caryopsis, or plant to produce compounds useful for mammalian usage, such as human insulin.

Some techniques are known for addressing some of those aims.

For example, the bacterium *Agrobacterium tumefaciens* has been used to introduce desired genes into the chromosome of a plant. For example the gene coding for EPSP synthase, a key enzyme in the synthesis of aromatic acids in plants, has been isolated and introduced into petunia plants under the control of a CaMV promoter (Shah *et al.*, [1986]). The transgenic plants expressed increased levels of EPSP synthase in their chloroplasts and were more tolerant to glycophophate - which inhibits production of EPSP synthase.

Other examples may be found in R.W. Old & S.B. Primrose (1993). Another use of *Agrobacterium tumefaciens* is described in De Silva *et al.* (1992) wherein a recombinant DNA construct is described containing a plant plastid specific promoter that expresses a gene placed under its control in concert with the fatty acid or lipid biosynthesis in the plant cell.

PCT WO 90/01551 mentions the use of the aleurone cells of mature, germinating caryopsis to produce proteins from GOIs under the control of an α-amylase promoter. This promoter is active only in germinating caryopsis.

Non-specific lipid transfer proteins (nsLtps) have the ability to mediate *in vitro* transfer of radiolabelled phospholipids from liposomal donor membranes to mitochondrial acceptor membranes (Kader *et al.*, 1984; Watanabe and Yamada, 1986). Although their *in vivo* function remains unclear, nsLTPs from plants have recently received much attention due to their recurrent isolation as cDNA clones representing developmentally regulated transcripts expressed in several different tissues. A common feature is that, at some point in their development, they are highly expressed in tissues producing an extracellular layer rich in lipids.

In particular, transcripts corresponding to cDNAs encoding 10 kDa nsLTPs have been characterized in the tapetum cells of anthers as well as the epidermal layers of leaves and shoots in tobacco (Koltunow *et al.*, 1990; Fleming *et al.*, 1992), and barley aleurone layers (Mundy and Rogers, 1986; Jakobsen *et al.*, 1989).

In addition, a 10 kDa nsLTP has been discovered to be one of the proteins secreted from auxin-treated somatic carrot embryos into the tissue culture medium (Sterk *et al.*, 1991).

Based on *in situ* hybridisation data demonstrating that the Ltp transcripts are localized in the protoderm cells of the somatic and zygotic carrot embryo, it was suggested that *in vivo* nsLTPs are involved in either cutin biosynthesis or in the biogenesis and degradation of storage lipids (Sossountzov *et al.*, 1991; Sterk *et al.*, 1991).

A nsLTP in *Arabidopsis* has been localized to the cell walls lending further support to an extracellular function of this class of proteins (Thoma *et al.*, 1993).

Recently, using a standard *in vitro* Ltp assay, two 10 kDa nsLtps and one member of a novel class of 7 kDa nsLtp's were isolated from wheat seeds (Monnet, 1990; Dieryck *et al.*, 1992).

The sequence of this 7 kDa wheat nsLtp protein shows a high degree of similarity with the predicted protein from the open reading frame (ORF) of the Bz11E cDNA, which had been isolated in a differential screening for barley aleurone specific transcripts (Jakobsen *et al.*, 1989). However, the amino acid sequence of this polypeptide showed only limited sequence identities with the previously sequenced 10 kDa proteins. In sub-cellular localisation studies using gold labelled antibodies one 10 kDa protein from *Arabidopsis* was localised to the cell wall of epidermal leaf cells. The presence of a signal peptide domain in the N-terminus of the open reading frames of all characterised plant nsLtp cDNAs, also suggests that these are proteins destined for the secretory pathway with a possible extracellular function.

Olsen *et al.* in a paper titled "Molecular Strategies For Improving Pre-Harvest Sprouting Resistance In Cereals" published in 1990 in the published extracts from the Fifth International Symposium On Pre-Harvest Sprouting In Cereals (Westview Press Inc.) describe three different strategies for expressing different "effector" genes in the aleurone layer in developing grains of transgenic plants. This document mentions 4 promoter systems - including a system called B11E.

Kalla *et al.* (1993) in a paper titled "Characterisation of Promoter Elements Of Aleurone Specific Genes From Barley" describe the possibility of the expression of anti-sense genes by the use of promoters of the aleurone genes B22E, B23D, B14D, and B11E.

Linnestad *et al.* (1991) describe the isolation and sequencing of the Ltp1 gene and disclose a 787 base pair fragment of the Ltp1 gene promoter fused to a fragment of the Ltp1 structural gene. This paper does not disclose any expression studies using the 787 base pair fragment.

Skriver *et al.* (1992) report further on the Ltp1 gene. This paper says that the Ltp1 gene promoter is only aleurone specific. To confirm this submission the paper further reports on the isolation and fusion of a 769 bp fragment (-702 to +67 bp) of the gene to the bacterial β-glucuronidase (*GUS*) reporter gene. This fragment therefore contains 635 bp of the Ltp1 gene promoter. Subsequent transient expression studies showed that the shortened gene promoter resulted only in aleurone specific expression. Expression was not observed in any other tissue. The authors conclude that there are sequences between the -702 and +67 bp of Ltp1 which contain DNA elements that specifically modulate its transcription in aleurone cells.

One of the major limitations to the molecular breeding of new types of crop plants with specific cells expressing GOIs is the lack of a suitable tissue specific promoter. In particular, there is a lack of a tissue specific promoter that leads to expression of a GOI in a developing caryopsis (or grain) or in a germinating rice seedling or in a developing grain, in particular in the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant.

Moreover, all of the available promoters - such as the CaMV 35S, rice actin and maize alcohol dehydrogenase - are constitutive, i.e. they are fairly non-specific in target site or stage development as they drive expression in most cell types in the plants.

Hence, another problem that arises is how to achieve expression of a product coded for by a GOI in a specific tissue that gives minimal interference with the developing embryo and seedling.

Our co-pending United Kingdom patent application (GB 9324707.0) describes the use of an Ltp2 gene promoter for expression of a GOI in the aleurone layer. However, in spite of this teaching, there is still a need for other tissue specific promoters, such as another aleurone specific promoter or, preferably, a promoter specific for vascular tissue and/or the scutellar epithelial layer. In this regard, it is still desirable to provide other tissue specific expression of GOIs in cereals such as rice, maize, wheat, barley and other transgenic cereal plants. Moreover it is desirable to provide tissue specific expression that does not detrimentally affect the developing embryo and the developing caryopsis (or grain).

According to a first aspect of the present invention there is provided a modified Ltp1 gene promoter which is integrated, preferably stably integrated, within a plant material's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

According to a second aspect of the present invetion there is provided a modified Ltp1 gene promoter according to claim 1 or claim 2 wherein the promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

According to a third aspect of the present invetion there is provided an isolated Ltp1 gene promoter comprising the sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology therewith, or a variant thereof.

According to a fourth aspect of the present invetion there is provided a construct comprising a GOI and a modified Ltp1 gene promoter according to the present invention; wherein the construct is capable of being expressed in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material; and wherein if there is expression in just the aleurone layer of a developing barley caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver

et al (1992).

According to a fifth aspect of the present invetion there is provided an expression system for at least the aleurone cells or for at least the scutellar epithelial tissue or vascular tissue of a plant material, the expression system comprising a GOI fused to a modified Ltp1 gene promoter wherein the expression system is capable of being expressed in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of the plant material; and wherein if there is expression in just the aleurone layer of a developing barley caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

According to a sixth aspect of the present invetion there is provided an expression system for at least the aleurone cells of a developing caryopsis or for at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem), the expression system comprising a gene promoter fused to a GOI wherein the expression system is capable of being expressed in at least the aleurone cells of the developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem); either wherein if there is expression in just the aleurone layer of a developing barley caryopsis then either the promoter is not the wild type Ltp1 promoter in its natural enviroment and the GOI is not the Ltp1 functional gene in its natural enviroment; or wherein if there is expression in just the aleurone layer of a developing caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

According to a seventh aspect of the present invetion there is provided a transgenic cereal comprising an expression system according to the present invention or a construct according to the present invention wherein the expression system or construct is integrated, preferably stably integrated, within the cereal's genomic DNA.

According to an eighth aspect of the present invetion there is provided the use of a gene promoter according to the present invention to induce expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material.

According to a ninth aspect of the present invetion there is provided a process of expressing a GOI when fused to a gene promoter according to the present invention wherein expression occurs in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material.

According to a tenth aspect of the present invetion there is provided a process of expressing in at least the scutellar epithelial tissue or vascular tissue of a developing grain or a germinating seedling or a plant, preferably a developing rice grain or a germinating rice seedling or a transgenic rice plant, an expression system according to teh present invention or a construct according to the present invention wherein the expression system or construct is integrated, preferably stably integrated, within the cereal's genomic DNA.

According to an eleventh aspect of the present invetion there is provided a combination expression system comprising a. as a first construct, a construct according to the present invention; and b. as a second construct, a construct comprising a GOI and another gene promoter that is tissue- or stage-specific.

According to a twelfth aspect of the present invetion there is provided a developing cereal grain, preferably a germinating rice seedling, comprising any one of: a promoter according to the present invention, an expression system according to the present invention, a construct according to the present invention, or a combination expression system according to the present invention.

According to a thirteenth aspect of the present invetion there is provided plasmid NCIMB 40609.

Preferably the plant material is a developing caryopsis, a germinating seedling, a developing grain or a plant.

Preferably the construct is capable of being expressed in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant when the construct is integrated, preferably stably integrated, within the caryopsis's or grain's or seedling's or plant's genomic DNA.

Preferably the modified Ltp1 gene promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

Preferably the construct further comprises at least one additional sequence to increase expression of the GOI.

Preferably the expression system is for at least the aleurone cells of a developing caryopsis or for at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem).

Preferably the expression system is additionally capable of being expressed in the embryo cells of the germinating grain or the plantlet.

Preferably the expression system is integrated, preferably stably integrated, within a developing caryopsis's genomic DNA or a germinating seedling's genomic DNA or a developing grain's genomic DNA or a plant's genomic DNA.

Preferably, in the expression system, the gene promoter comprises the sequence shown as SEQ I.D. No. 1 or comprises a sequence that has substantial homology therewith, or is a variant thereof.

Preferably, the expression system comprises the construct according to the present invention.

Preferably, in the use, the gene promoter is used to induce expression of a GOI when fused to the gene promoter in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

Preferably, the gene promoter expresses the GOI when fused to the gene promoter in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

Preferably the promoter and GOI are integrated, preferably stably integrated, within a cereal's genomic DNA.

Preferably the gene promoter is a fragment of a barley Ltp1 gene promoter.

Preferably the promoter is for a 10 kDa lipid transfer protein.

Preferably the gene promoter is obtainable from plasmid NCIMB 40609.

Preferably the gene promoter is used for expression of a GOI in a cereal caryopsis or a cereal grain or a cereal seedling or a cereal plant.

Preferably the cereal caryopsis is a developing cereal caryopsis, the cereal grain is a developing cereal grain, and the cereal seedling is a germinating cereal seedling.

Preferably the cereal is any one of a rice, maize, wheat, or barley.

Preferably the cereal is rice or maize.

Preferably the developing caryopsis is a developing barley caryopsis, the germinating seedling is a germinating rice seedling, the developing grain is a developing rice grain, and the plant is a transgenic rice plant.

Preferably in the combination expression system each construct is integrated, preferably stably integrated, within a plant material.

Preferably each of the myb site and the myc site in the gene promoter is maintained substantially intact.

Preferably the gene promoter is integrated, preferably stably integrated, in the developing caryopsis's genomic DNA or the germinating seedling's genomic DNA or the developing grain's genomic DNA or the plant's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells of the developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

Preferably the transgenic developing caryopsis, germinating seedling, developing grain or plant is prepared by stable integration of the GOI and the gene promoter to form a stable transgenic plant. This ensures aleurone or epithelial or vascular expression at, at least, the developing caryopsis stage. One preferred method for achieving this includes preparing the transgenic developing caryospis, germinating seedling, developing grain or plant by stable integration of the GOI and the gene promoter at the protoplast level.

Preferably the promoter is used for expression of a GOI in a monocotyledonous species, including a grass - preferably a transgenic cereal grain or caryopsis. Preferably the gene promoter is used for expression of a GOI in a cereal grain or caryopsis. Preferably the cereal grain or caryopsis is a developing cereal grain or caryopsis. Preferably the cereal grain or caryopsis is any one of a rice, maize, wheat, or barley grain or caryopsis.

Preferably the cereal grain is a rice grain.

Preferably the DNA sequence for the modified Ltp1 gene promoter is the nucleic acid sequence shown as SEQ. I.D. 1.

Preferably in the combination expression system each construct is integrated, preferably stably integrated, within a developing caryopsis's genomic DNA or a grain's genomic DNA or a seedling's genomic DNA or a plant's genomic DNA.

Preferably, in the combination expression system, the first construct comprises the modified Ltp1 gene promoter according to the present invention.

Preferably, the promoter in the second construct is an aleurone specific promoter.

Preferably the promoter in the second construct a barley promoter.

Preferably the second construct is the B22E gene promoter.

Preferably the promoter in the second construct is the Ltp2 gene promoter.

Preferably the promoter in the second construct is for a 7 kDa lipid transfer protein.

Preferably the promoter in the second construct is the promoter for Ltp2 of *Hordeum vulgare*.

Preferably the promoter in the second construct comprises the sequence shown as SEQ. I.D. 2, or a sequence that has substantial homology therewith, or a variant thereof.

Preferably each of the myb site and the myc site in the Ltp2 gene promoter is maintained substantially intact.

Preferably the second construct further comprises at least one additional sequence to increase expression of the GOI.

Preferably, in the combination expression system, the grain or caryopsis is as defined above for the present invention.

Preferably the gene promoter is obtainable from plasmid NCIMB 40609.

A preferred embodiment of the present invention is a modified Ltp1 gene promoter which is integrated, preferably stably integrated, within a plant material's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem), but wherein if there is expression in just the aleurone layer of a developing seed then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

An even more preferred embodiment of the present invention is a modified Ltp1 gene promoter which is integrated, preferably stably integrated, within a plant material's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem), wherein the promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

As a highly preferred embodiment, the present invention therefore provides transgenic rice comprising a construct comprising a GOI fused to a modified Ltp1 gene promoter; wherein the construct is integrated, preferably stably integrated, within the rice's genomic DNA, and wherein the GOI is expressed in at least the vascular tissue and/or scutellar epithelial layer of a germinating rice seedling or a developing rice grain or a rice plant.

In a more preferred embodiment the present invention provides a transgenic rice seedling, grain or plant comprising a construct comprising a GOI fused to a modified Ltp1 gene promoter, wherein the construct is integrated, preferably stably integrated, within the rice's genomic DNA; wherein the GOI is expressed in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant, and wherein the modified Ltp1 gene promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

The additional sequence(s) for the construct(s) for increasing the expression of the GOI(s) may be one or more repeats (e.g. tandem repeats) of the promoter upstream box(es) which are responsible for the aleurone layer or scutellar epithelial cell and/or vascular expression pattern of the modified Ltp1 gene promoter. The additional sequence may even be a *Sh1*-intron.

The term "plant material" includes a developing caryopsis, a germinating caryopsis or grain, or a seedling, a plantlet or a plant, or tissues or cells thereof, such as the aleurone cells of a developing caryopsis or the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem).

Thus a preferred aspect of the present invention comprises plant material comprising a GOI and a modified Ltp1 gene promoter which is capable of inducing expression of the GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of the plant material; wherein the construct is capable of being expressed in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of the plant material, when the construct is integrated, preferably stably integrated, within the caryopsis's or grain's or seedling's or plant's genomic DNA; and wherein the modified Ltp1 gene promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

The term "modified" with reference to the present invention means any Ltp1 gene promoter that is different to the wild type promoter but wherein the promoter induces expression in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

In particular, a preferred modified Ltp1 gene promoter is a shortened wild type Ltp1 gene promoter but wherein the promoter induces expression in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

The term "transgenic" in relation to the present invention - in particular in relation to the developing caryopsis, germinating seedlings, developing grains and plants of the present invention - does not include a wild type promoter in its natural enviroment in combination with its associated functional gene (GOI) in its natural enviroment. Thus, the term includes developing caryopsis or seedlings or grains or plants incorporating the GOI which may be natural or non-natural to the grain or caryopsis or seedling or grain or plant in question operatively linked to the modified Ltp1 promoter of the present invention.

The term "GOI" with reference to the present invention means any gene of interest. A GOI can be any gene that is either foreign or natural to the cereal in question, except for the wild type Ltp1 functional gene when in its natural enviroment. In the combination expression system the GOI may be the same or different.

Typical examples of a GOI include genes encoding for proteins and enzymes that modify metabolic and catabolic processes. For example, the GOI may be a protein giving added nutritional value to the grain or caryopsis as a food or crop. Typical examples include plant proteins that can inhibit the formation of anti-nutritive factors and plant proteins that have a more desirable amino acid composition (e.g. a higher lysine content than the non-transgenic plant).

The GOI may even code for an enzyme that can be used in food processing such as chymosin, thaumatin, α-galactosidase and guar.

In a preferred embodiment, particularly with vascular expression, the GOI may code for an agent for introducing or increasing pathogen resistance.

The GOI may even be an antisense construct for modifying the expression of natural transcripts present in the relevant tissues.

The GOI may even code for a non-natural plant compound that is of benefit to animals or humans. For example, the GOI could code for a pharmaceutically active protein or enzyme such as the therapeutic compounds insulin, interferon, human serum albumin, human growth factor and blood clotting factors. In this regard, the transformed cereal grain or caryopsis could prepare acceptable quantities of the desired compound which could be easily retrievable from the scutellar epithelial layer, the aleurone layer or the vascular tissue.

Preferably the GOI is a gene encoding for any one of a protein having a high nutritional value, a *Bacillus thuringensis* insect toxin, an α- or β- amylase antisense transcript, a protease antisense transcript, or a glucanase antisense transcript.

The term "a variant thereof" with reference to the present invention means any substitution of, variation of, modification of, replacement of, deletion of or the addition of one or more nucleic acid(s) from or to the promoter sequence providing the resultant sequence exhibits at least aleurone, scutellar epithelial or vascular expression, respectively. The term also includes sequences that can substantially hybridise to the promoter sequence.

The term "substantial homology" covers homology with respect to at least the essential nucleic acids/nucleic acid residues of the promoter sequence providing the homologous sequence acts as a promoter, e.g. as a promoter for at least aleurone expression in a developing caryopsis or for at least scutellar epithelial tissue or

vascular tissue expression in a germinating seedling or in a developing grain or plant. Preferably there is at least about 80% homology, more preferably at least about 90% homology, and even more preferably there is at least about 95% homology with the promoter sequence shown as SEQ. I.D. No. 1. or SEQ. I.D. No. 2, respectively.

The term "maintained substantially intact" means that at least the essential components of each of the myb site and the myc site remain in the construct to ensure acceptable expression of a GOI. Preferably at least about 75%, more preferably at least about 90%, and even more preferably there is at least about 95%, of the myb or myc site is left intact.

The term "construct" - which is synonymous with terms such as "cassette", "hybrid" and "conjugate" - includes a GOI directly or indirectly attached to the modified gene promoter, such as to form a [modified Ltp1 gene promoter-GOI] cassette. An example of an indirect attachment is the provision of a suitable spacer group such as an intron sequence, such as the *Sh1*-intron, intermediate the promoter and the GOI. The same is true for the term "fused" in relation to the present invention which includes direct or indirect attachment.

The term "expression system" means that the system defined above can be expressed in an appropiate organism, tissue, cell or medium. In this regard, the expression system of the present invention may comprise additional components that ensure ro increase the expression of the GOI by use of the gene promoter.

As indicated above, the expression system of the present invention can also be used in conjunction with another expression system, preferably an expression system that is also tissue and/or stage specific.

For example, the construct comprising the modified Ltp1 gene promoter (e.g. the 787 bp fragment of SEQ. I.D. NO. 1) can be used in conjunction with a construct comprising the Ltp2 gene promoter (e.g. SEQ. I.D. NO. 2) - which is the subject of our co-pending UK patent application GB 9324707.0.

In this respect, and with reference to barley, in the early stages of developing caryopsis the modified Ltp1 gene promoter affects expression of a GOI in at least the aleurone layers of developing caryopsis. This expression can then be complimented by use of the Ltp2 gene which can express a GOI (which may be the same or different as that operatively linked to the modified Ltp1 gene promoter) in high levels in the aleurone layer of developing grains.

However, the combination expression system is very effective for transgenic rice. In this respect, in the early stages of developing caryopsis the modified Ltp1 gene promoter expresses a GOI in the scutellar epithelial layer and the vascular tissue. This expression can then be complimented by use of the Ltp2 gene which can express a GOI in high levels in the aleurone layer of developing grains. This combination is particularly advantageous for pre-harvest sprouting when the first response is production of α-amylase in the scutellar epithelium cells as this can be reduced or prevented by placing an anti-sense α amylase gene under the control of the Ltp1 promoter. In this system, the expression of antisense α-amylase would block the synthesis of α-amylases in the scutellum epithelial cells - where they are first made. The same or another GOI could be expressed in the aleurone layer *via* the Ltp2 gene promoter.

The construct comprising the modified Ltp1 gene promoter may even be used in conjunction with a construct comprising the B22E gene promoter - details of which may be found in Olsen *et al.* (1990) and Klemsdal *et al.*, (1991). This gene promoter, which is expressed in immature aleurone layers, has been shown by particle bombardment experiments to be capable of driving *Gus* expression in developing barley grains. Also, using Northern analysis, as well as *in situ* hybridization, it has been shown that the B22E cDNA probe hybridizes to transcripts in the aleurone layer and in the scutellum parenchyma cells and the provascular bundle of the embryo axis in developing barley grains. In addition, a hybridizing transcript is also present in the ventral vascular strand of developing caryopsis (Olsen *et al.*, 1990).

We have also found that by using a 4.6 kb B22E promoter fragment contained on a XbaI-ClaI fragment of a genomic clone fused to the *Gus* reporter gene transformed rice plants could be prepared. Those transformed rice plants exhibited strong expression in the vascular tissue (phloem) of the ventral strand of the developing rice grain. This expression pattern was completely unexpected in view of Klemsdal *et al* (1991). Expression, although weaker, in the same cell type was also observable in the stem of young shoots. Thus, using the B22E promoter, a GOI transcript can be expressed in the aleurone layers of developing grains, the parenchyma cells of the embryonic scutellum and the ventral vascular bundle of developing grains.

The combination of the use of the modified Ltp1 gene promoter and the B22E gene promoter could even include the use of another gene promoter, such as the Ltp2 gene promoter, to express three GOIs respectively wherein each GOI may be the same or different.

One or more of the other expression systems to be used in conjunction with the modified Ltp1 gene promoter expression system may be contained in or on the same transmission vector - such as in the same transforming baterium or even in the same plasmid. The advantage of this is that each expression system can then be delivered at the same time. The respective expression systems will then be turned on during the relevant life time of the grain or caryopsis or the plantlet or the mature plant.

The present invention therefore provides the novel and inventive use of a promoter which can express a GOI in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem). In a preferred embodiment the present invention relates to the use of a modified Ltp1 gene promoter, preferably the Ltp1 gene promoter is obtainable from barley.

The main advantage of the present invention is that the use of the modified Ltp1 gene promoter results in expression of a GOI in at least the aleurone layer of at least a developing caryopsis, such as a developing barley caryopsis, or in at least the

scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or plant of cereals such as rice, maize, wheat or other transgenic cereal grain or caryopsis, preferably a developing rice grain.

Another advantage is that, depending on the type of GOI, the expressed products can be stable *in vivo*. Hence over a period of time high levels of the expressed product can accumulate in the aleurone cells or in epithelial cells or in the vascular tissue.

A further advantage is that the expression of the product coded for by a GOI in the aleurone layer or the epithelial layer or the vascular tissue has minimal interference with the developing embryo and seedling. This is in direct contrast to known constitutive promoters which give high levels of expression in the developing seedling and mature plant tissues which severely affect normal plant development. Thus the present invention is particularly useful for expressing a GOI in at least the aleurone layer of a developing caryopsis or in at least the scutellar epithelial tissue or in the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or plant - such as cereal grains or caryopsis - and in doing so not detrimentaly affect the caryopsis, seedling, grain or plant.

With regard to the first aspect of the present invention it is to be noted that this is the first reported case for the specific expression of a GOI in the scutellar epithelial cells or vascular cells of a transformed developing cereal grain such as rice.

With regard to some aspects of the present invention, it is to be noted that up until now it was believed that the wild type Ltp1 gene promoter or a specific varaint thereof when fused to at least a segment of the Ltp1 fucntional gene would lead only to expression in the aleurone layer. For example see the teachings of Skriver *et al.* (1992). However, with the present invention, we have now surprisingly found that this is not the case and it is now possible to modify the Ltp1 gene promoter to lead to a pronounced expression in at least the aleurone layer or in at least the scutellar epithelial layer or vascular tissue of a plant material.

In one embodiment the plant material is barley plant material. In another embodiment the plant material is not barley plant material. In a preferred embodiment the plant material is rice plant material. In an alternative preferred embodiment the plant material is maize plant material.

In a germinating, transgenic barley caryopsis according to the present invention, there is expression in the aleurone layer.

In a germinating, transgenic rice seedling according to the present invention there is pronounced expression in the scutellar epithelial tissue and vascular tissue.

As indicated, the expression pattern for the present invention is particularly surprising as it was completely unexpected that a modified Ltp1 gene promoter could result in expression of a GOI, such as a plant functional gene, in the aleurone cells of, for example, barley or in the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or plant of rice (see experimental section later). The findings of the present invention are also surprisingly different to the work of Skriver *et al.* (1992) who, as mentioned above, report that the Ltp1 gene promoter and a shortened version thereof when fused to the functional Ltp1 functional gene only result in aleurone specific expression in barley - i.e. expression is not observed in any other tissue in barley or even other cereals.

In order to prepare the transgenic organism according to the present invention, the modified Ltp1 gene promoter may be initially inserted into a plasmid. For example, the *Sac*I-*Bcl*I Ltp1 gene promoter fragment can be inserted into the *Sac*I-*BamH*I site of Bluescript. A GOI, such as *GUS*, can then be inserted into this construct. Furthermore, a *Sh*1 intron can then be inserted into the *Sma*I site of this construct.

Stable integration into protoplasts may be achieved by using the method of Shimamoto (1989). Another way is by bombardment of an embryonic suspension of cells (e.g. rice, barley or maize cells). A further way is by bombardment of immature embryos (e.g. rice, maize or barley embryos).

With regard to the present invention, it is shown by using particle bombardments that the modified Ltp1 gene promoter, such as the 787 bp fragment of the attached sequence, when fused to a β-glucuronidase (*GUS*) reporter gene, which serves as a GOI for the purposes of this invention, acts as a promoter for expression of *GUS* in a specific tissue type or specific tissue types. For example, *GUS* expression can be achieved in the aleurone cells of developing cereal caryopsis or grain, in particular developing barley caryopsis, or in the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or plant, in particular developing rice grain or germinating seedlings.

In particular, in transgenic rice plants, the modified barley Ltp1 gene promoter directs strong expression of the *GUS*-reporter gene in the scutellar epithelial layer and the vascular tissue of the developing caryopsis. This expression can continue through into the germinating grains. The surprising finding is that very pronounced expression can be seen in the scutellar epithelial tissue or vascular tissue of a developing rice grain or germinating rice seedlings. Other examples include expression in the vascular bundles and tip of emerging shoots and roots, leaf veins and vascular bundles of stems.

Generally therefore the present invention relates to a modified promoter for a Ltp1 gene encoding a 10 kDa nsLTP. In the present invention, a genomic clone was isolated using the cDNA insert of previously isolated cDNA clone and characterised by DNA sequencing (see discussion later). The sequence of the cDNA and isolated genomic clone was found to be identical in the overlapping region. It was found the Ltp1 gene contains one intron (see discussion later).

By comparing the DNA sequence of the active promoter sequences two putative *cis*-acting elements with the potential of binding known transcriptional factors present in cereals were detected. They include the binding sites for transcriptional factors of the myb and myc class, namely TAACTG and CANNTG respectively. Our studies showed that high levels of expression are achieved when the myb and myc sites are left intact.

In the present invention, mature fertile rice plants were regenerated from transformed cultured rice protoplasts. The developing caryopsis of these primary transformants were analysed for the expression of *GUS*. It was found that the modified barley Ltp1 gene promoter confers some expression in the aleurone layer of the transgenic rice plants. However, pronounced expression was observed in the scutellar epithelial tissue or vascular tissue of germinating rice seedlings or developing transgenic rice grain or transgenic rice plants. This is the first example of such patterns of expression in transgenic rice plants.

The following sample has been deposited in accordance with the Budapest Treaty at the recognised depositary The National Collections of Industrial and Marine Bacteria Limited (NCIMB) at 23 St Machar Drive, Aberdeen, Scotland, AB2 1RY, United Kingdom, on 11 January 1994:

> An *E. Coli* K12 bacterial stock containing the plasmid pLtp1.787-GN - i.e. Bluescript containing a 787 bp fragment of the barley Ltp1 gene promoter (Deposit Number NCIMB 40609).

The plasmid pLtp1.787-GN is shown pictorially in Figure 6 (see later).

The modified Ltp1 gene promoter can be isolated from this plasmid through the use of appropriate PCR primers, which may be easily constructed from the data from the shown sequences.

Other embodiments and aspects of the present invention include:

> A transformed host having the capability of expressing a GOI in the aleurone layer or the scutellar epithelial layer or the vascular tissue through the use of the gene promoter as hereinbefore described;

> A vector incorporating a construct as hereinbefore described or any part thereof;

A plasmid comprising a construct as hereinbefore described or any part thereof;

A cellular organism or cell line transformed with such a vector;

A monocotylenedonous plant comprising any one of the same;

A developing caryopsis or grain or germinating seedling comprising any of the same; and

A method of expressing any one of the above.

The present invention will now be described only by way of examples in which reference shall be made to the accompanying Figures in which:

Figure 1 is a diagrammatic illustration of the structural components of a developing caryopsis;

Figure 2 shows the results for an *in situ* hybridization experiment for a wild type Ltp1 gene promoter in barley;

Figure 3 is a nucleotide sequence of part of the wild type Ltp1 gene taken from Linnestad *et al.* (1991);

Figure 4 is a nucleotide sequence of part of the wild type Ltp1 gene taken from Skriver *et al.* (1992);

Figure 5 is a nucleotide sequence of a 787 bp fragment of the wild type Ltp1 gene promoter;

Figure 6 is a linear map of the Ltp1.787-GN construct showing additional sequence information;

Figure 7 is a circular map of the plasmid pLtp1.787-GN containing the Ltp1.787-GN construct;

Figure 8 is a longitudinal section of a developing rice grain post expression of the modified Ltp1 gene promoter; and

Figure 9 is a longitudinal section of a mature germinating rice grain post expression of the modified Ltp1 gene promoter.

A. METHODS

i. Plant material

Caryopsis of barley (*Hordeum vulgare* cv. Bomi) were collected from plants grown in a phytotron as described before (Kvaale and Olsen, 1986). The plants were emasculated and pollinated by hand and isolated in order to ensure accurate determination of caryopsis age.

ii. cDNA and genomic clones

The isolation and sequencing of the Ltp1 cDNA clone was conducted as described by Jakobsen *et al.* (1989). A barley, cv. Bomi genomic library was constructed by partial *Mbo*I digestion of total genomic DNA and subsequent ligation of the 10-20 kilo basepair (kb) size fraction with *Bam*HI digested lambda EMBL3 DNA (Clontech Labs, Palo Alto, Ca, USA). Using the Ltp1 cDNA insert as a template for probe synthesis with a random labelling kit (Boehringer-Mannheim), one positive clone was identified after repeated rounds of plaque hybridization. DNA purified from this clone was restricted with several enzymes and characterized by Southern blot analysis. The sequence data obtained after this procedure are shown in Figure 3.

iii. *In situ* hybridization

For *in vitro* transcription of antisense RNA, the plasmid Ltp1 was linearized and transcribed using MAXIscript (Ambion) and [α ^{33}P]-UTP (Amersham International). The probe was hydrolysed to fragments of about 100 bp as described by Somssich *et al.* (1988). Caryopsis tissues were fixed in 1% glutaraldehyde, 100 mM sodium phosphate (pH 7.0) for 2 hours and embedded in Histowax (Histolab, Göteborg, Sweden).

Barley caryopsis sections of 10 μm were pre-treated with pronase (Calbiochem) as described by (Schmelzer *et al.*, 1988) and hybridized with 25 ml of hybridization mix (200 ng probe ml-1, 50% formamide, 10% (w/v) dextran sulphate, 0.3 M NaCl, 10 mM Tris-HCl, 1 mM EDTA (pH 7), 0.02% polyvinyl-pyrrolidone, 0.2% Ficoll, 0.02% bovine serum albumin) for 15 hours at 50 °C.

Post-hybridization was carried out according to Somssich *et al.* (1988) and autoradiography was done as described by Schmelzer *et al.* (1988).

iv. Constructs for transient expression analysis

For the micro-projectile bombardment experiments, the following was used:

pLtp1.787-GN (see Figure 7 and associated commentary).

Isolated plasmid DNA was used in the bombardment studies.

For transient assay studies with rice protoplasts, the following were studied:

pLtp1.787-GN (see Figure 7 and associated commentary).

pLtp1.787(*-myb/myc*)-GN (see commentary below).

Deletion studies were performed on the modified Ltp1 gene promoter (Ltp1.787) wherein a section of DNA containing the myb and myc sites (see Figure 3 and associated commentary) was removed to form pLtp1.787(*-myb/myc*)-GN. In this embodiment, the modified Ltp1 gene promoter having deletions from and between the myb and myc sites was prepared and fused to GN. In order to prepare this deleted modified Ltp1 gene promoter a PCR strategy using primers covering the flanking sequences of the deleted sequence was adopted.

v. Transformation of barley cells by particle bombardment

Barley caryopsis were harvested at 25 DAP (days after pollination), surface sterilized in 1% sodium hypochlorite for 5 min and then washed 4 times in sterile distilled water. The maternal tissues were removed to expose the aleurone layer and the caryopsis was then divided into two, longitudinally along the crease. The pieces of tissue were then placed, endosperm down, onto MS media (Murashige & Skoog 1962) with 10 g/l sucrose solidified with 10 g/l agar in plastic petri dishes (in two rows of 4 endosperm halves per dish). Embryos from the same caryopsis were placed in the same petri dishes with the scutellum side facing upwards.

Single bombardments were performed in a DuPont PDS 1000 device, with M-17 tungsten pellets (approx. 1 μm in diameter) coated with DNA as described by Gordon-Kamm *et al.* (1990) and using a 100 mm mesh 2 cm below the stopping plate. Histochemical staining for *GUS* expression was performed with X-Gluc (5-bromo,4-chloro,3-indolyl,ß-D,Glucuronic acid) as described by Jefferson (1987) at 37°C for 2 days.

In these studies, after bombardment with the pLTp1.787-GN and staining for *GUS*-activity, blue spots appeared both in the aleurone layer as well as in the scutellar epithelium layer. These results demonstrate that the 787 bp fragment of the Ltp1 gene promoter of the present invention is capable of driving transcription in the epithelial cells.

vi. Rice transformation

In these studies, the gene was transformed into rice by electroporation of embryogenetic protoplasts following the teachings of Shimamoto et al. 1989. Six fertile transgenic rice plants were obtained. Histochemical *GUS* analysis was also carried out with developing rice grains of 25 DAP and 1 to 5 day old seedings and up to 1 month old plants derived from transgenic grains. The results demonstrated expression of the Ltp1 - *GUS* gene in the scutellar epithelial layer of developing transgenic rice plants. In addition, in a germinating rice seedling according to the present invention there is a pronounced expression in the vascular tissue.

B. RESULTS AND DISCUSSION WITH REFERENCE TO THE FIGURES

1. In order to explain more fully the results, reference is made to Figure 1 which shows the major components of a typical developing caryopsis (or grain) 1. In this regard, the caryopsis (or grain) 1 comprises an endosperm component 3 and an embryo component 5. The endosperm component 3 is divisible into an outer aleurone layer 7, which is three cells thick for barley caryopsis, and a starchy endosperm 9. The embryo component 5 is divisible into a scutellum 11 and an embryo axis 13. The scutellum 11 is further divisible into an epithelial layer 15 and parenchyma layer 17. Likewise, the embryo axis 13 is further divisible into a root component 19 and a shoot component 21.

2. Figure 2 is a transverse section of a 30 day-old wild-type developing barley caryopsis showing *in situ* hybridisation with a radio-labelled Ltp1 probe. The bound probe is only seen in the aleurone layer. It is not seen in any other tissue type, in particular the scutellar epithelial layer. This work confirms the work of Skriver *et al.* (1992).

The bright spots are due to optical interference.

3. Figure 3 shows the nucleotide sequence and the deduced amino acid sequence of Ltp1. The intron is indicated by lower case letters. The TGA stop codon is indicated by an asterisk, the putative CAAT and TATA sequences are indicated by boxes. A 21 bp inverted repeat is indicated by arrows. Four 8 bp palindromic sequences are overlined. The motif indicated by thick underlining resembles the CATGTAAA motif present in the promoters of several genes expressed in aleurone cells (Klemsdal *et al.* (1991)). An AT block followed by a myb consensus recognition site and a myc binding motif are indicated by double underlining.

4. Figure 4 shows the sequence of the Ltp1 gene. The 351 bp open reading frame is interrupted by a 133 bp intron (+412 to +544). The transcript start site is at position +1. The putative CAAT and TATA boxes are at -107 and -34. A putative poly (dA) site is at +785 (Skriver *et al.* (1992)).

5. Figure 5 is the nucleotide sequence of the preferred embodiment of the present invention, i.e. a 787 bp fragment of the Ltp1 gene promoter. The same commentary for Figure 3 is equally applicable here.

6. Figure 6 is an outline of the Ltp1 genomic clone containing the Ltp1 structural gene (shaded box) and the promoter fragment fused to the *GUS* gene (black box) used to transform rice. Also indicated are the extensions of the Ltp1 fragment described in Linnestad *et al.* (1991) and Skriver *et al.* (1992). The figures used represent DNA fragment lengths in kb. The total length of the genomic clone is in the order of 8.1 kb.

7. Figure 7 helps explain how pLtp1.787-GN was constructed. In this regard, the following fragments were sequentially cloned into the vector Bluescript KS$^-$: firstly the 787 bp SacI/Bcl fragment of the Ltp1 gene promoter was cloned into the SacI/BclI site of the vector; and secondly a *GUS*-Nos Terminator on 2150 bp SmaI/EcoRI fragment derived from pBI101 was cloned into SmaI/EcoRI downstream of the Ltp1 promoter.

8. Figure 8 is a longitudinal section of a 30 day old transgenic rice grain showing transcriptional activity of the construct of Figure 7 (i.e. pLtp1.787-GN) containing the promoter of Figure 5. It is to be noted that transcriptional activity is achieved in the scutellar epithelial layer, as denoted by the blue staining.

9. Figure 9 is a longitudinal section of a mature germinating transgenic rice grain showing transcriptional activity of the construct of Figure 7 (i.e. pLtp1.787-GN) containing the promoter of Figure 5.

It is to be noted that transcriptional activity is achieved in the scutellar epithelial layer. Transcriptional activity is also observed in the shoot epithelial layer and in the aleurone layer. However, the extent of expression in the last two tissue types is not as pronounced as that in the scutellar epithelial layer.

However, more importantly, with the transgenic rice transcriptional activity is observed in the vascular tissue of the germinating seedling and the vascular tissue of the root and stem.

C. SUMMATION

The Examples relate to the isolation of and to the use of a 787 bp fragment of the promoter for the barley Ltp1 gene, which encodes a 10 kDa nsLTP. The gene was isolated by the use of a cDNA from a differential screening experiment in which the positive probe was constructed from aleurone cell poly (A) rich RNA, and the negative probe from the starchy endosperm of immature grains.

A construct comprising the Ltp1 gene promoter fragment and a GOI (in this case *GUS*) was stably inserted into rice protoplasts.

Expression and *in situ* analysis for the wild type gene promoter demonstrated that the Ltp1 transcript is expressed in high levels only in the aleurone cells in developing barley caryopsis. This expression continued in germinating grains and also in

plantlets and mature plants.

However, for transgenic cereals, especially rice, even though there is some expression in the aleurone layer for the modified Ltp1 gene promoter it is, however, not as pronounced as that in each of the epithelial cells of the scutellum, the epidermal cells of the coleoptile and the vascular strands of the embryo of developing caryopsis (or grain).

This result is completely unexpected as it shows that a modified Ltp1 promoter can function differently in transgenic cereals, especially rice, than the wild-type Ltp1 gene in barley.

Expression and histochemical analysis for the transgenic rice demonstrated that the Ltp1 transcript is expressed in high levels in the scutellar epithelial tissue and vascular tissue, especially of a germinating rice seedling and a developing rice grain and a rice plant (e.g. in the root, leaves and stem). This expression continued in germinating grains and also in plantlets and mature plants.

Importantly, for rice, expression is observed in the vascular tissue of the germinating seedling and the vascular tissue of the root and stem.

This result is completely unexpected in view of the expression pattern of wild-type Ltp1 gene in barley.

Using the 787 bp promoter fragment in particle bombardments of developing barley caryopsis, we obtained activity (blue spots) in the epithelium layer of the scutellum.

The results therefore indicate that the modified Ltp1 gene promoter directs expression of a GOI predominantly in the aleurone cells of developing caryopsis, particularly for barley, or the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem) particularly for rice.

The modified Ltp1 gene promoter therefore represents a valuable tool for the expression of GOIs in the aleurone layer of developing caryopsis, in particular developing barley caryopsis.

Moreover, the modified Ltp1 gene promoter represents a valuable tool for the expression of GOIs in the scutellar epithelial cells and vascular cells of germinating seedlings or developing grain, in particular developing or germinating rice seedlings or grain. The epithelial or vascular expression is of particular benefit because the 787 bp LTP1 gene fragment can be used to express antisense α-amylase in the scutellar epithelial layer in order to reduce or to prevent damage due to preharvest sprouting or to introduce or enhance pathogen resistance.

One possible reason for the expression activity of the modified Ltp1 gene promoter of the present invention may be the absence of "silencer" elements in the modified gene promoter which prevent expression of the wild type gene in, for example, the scutellar epithelial layer and vascular cells. Accordingly, the term "modified" (as defined above) could include removal of any silencer elements from the wild type Ltp1 gene promoter.

Studies with the modified Ltp1 gene promoter having deletions from and between the myb and myc sites when fused to GN showed that the relative activity of the deleted modified Ltp1 gene promoter was less (in some cases 70% less) than the modified Ltp1 gene promoter which contains the myb and myc sites. Therefore, it is believed that the presence of the myb and myc sites are important for even higher levels of expression of the modified Ltp1 promoter in at least protoplasts of at least rice.

Accordingly the present invention also covers a method of enhancing the *in vivo* expression of a GOI in at least the aleurone layer of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant preferably of an embryo of a developing monocotyledon grain or caryopsis, comprising stably inserting into the genome of those cells a DNA construct comprising a modified Ltp1 gene promoter and a GOI, wherein in the

formation of the construct the modified Ltp1 gene promoter is ligated to the GOI in such a manner that each of the myb site and the myc site in the modified Ltp1 gene promoter is maintained substantially intact.

The present invention also covers the use of a myb site and a myc site in a modified Ltp1 gene promoter to enhance *in vivo* expression of a GOI in at least the aleurone layer of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant, preferably of an embryo of a developing monocotyledon caryopsis or grain, wherein the modified Ltp1 gene promoter and the GOI are integrated into the genome of the monocotyledon.

Each of these aspects is applicable to the combination expression system.

D. CONCLUSIONS VIS-A-VIS THE SPECIFIC EXAMPLES

1. The barley Ltp1 gene encodes a protein homologous to the 10 kDa wheat lipid transfer protein.

2. The wild type Ltp1 gene promoter is expressed in developing barley aleurone cells.

3. The modified Ltp1 gene promoter is transiently expressed in developing barley scutellar epithelial cells after particle bombardment.

4. The modified Ltp1 gene promoter directs expression of the *GUS*-reporter gene in the scutellar epithelial cells of developing transgenic rice grains. However, more pronounced expression is observed in the vascular tissue of germinating seedlings and the root and stem of the transgenic rice plant.

5. The modified Ltp1 gene promoter contains sequence elements implicated in the transcriptional control of cereal endosperm specific genes.

6. The modified Ltp1 gene promoter contains myb and myc sequence elements that are implicated in the level of transcription in cereal endosperm.

Other modifications of the present invention will be apparent to those skilled in the art without departing from the scope of the invention.

INDICATIONS RELATING TO A DEPOSITED MICROORGANISM

(PCT Rule 13*bis*)

A. The indications made below relate to the microorganism referred to in the description on page 24, lines 15-17

B. IDENTIFICATION OF DEPOSIT — Further deposits are identified on an additional sheet ☐

Name of depositary institution

The National Collections of Industrial and Marine Bacteria Limited (NCIMB)

Address of depositary institution *(including postal code and country)*

23 St. Machar Drive
Aberdeen
Scotland
AB2 1RY
United Kingdom

Date of deposit	Accession Number
11. JAN. 1994	NCIMB 40609

C. ADDITIONAL INDICATIONS *(leave blank if not applicable)* — This information is continued on an additional sheet ☐

In respect of those designations in which a European patent is sought, and any other designated state having equivalent legislation, a sample of the deposited microorganism will be made available until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or withdrawn or is deemed to be withdrawn, only by the issue of such a sample to an expert nominated by the person requesting the sample. (Rule 28(4) EPC).

D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE *(if the indications are not for all designated States)*

E. SEPARATE FURNISHING OF INDICATIONS *(leave blank if not applicable)*

The indications listed below will be submitted to the International Bureau later *(specify the general nature of the indications e.g., "Accession Number of Deposit")*

For receiving Office use only	For International Bureau use only
☐ This sheet was received with the international application	☐ This sheet was received by the International Bureau on:

CLAIMS

1. A modified Ltp1 gene promoter which is integrated, preferably stably integrated, within a plant material's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

2. A modified Ltp1 gene promoter according to claim 1 wherein the plant material is a developing caryopsis, a germinating seedling, a developing grain or a plant and wherein the gene promoter is integrated, preferably stably integrated, in the developing caryopsis's genomic DNA or the germinating seedling's genomic DNA or the developing grain's genomic DNA or the plant's genomic DNA and which is capable of inducing expression of a GOI when fused to the gene promoter in at least the aleurone cells of the developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

3. A modified Ltp1 gene promoter according to claim 1 or claim 2 wherein the promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

4. An isolated Ltp1 gene promoter comprising the sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology therewith, or a variant thereof.

5. A construct comprising

a GOI and

a modified Ltp1 gene promoter according to any one of claims 1 to 4;

wherein the construct is capable of being expressed in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material; and

wherein if there is expression in just the aleurone layer of a developing barley caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

6. A construct according to claim 5 wherein the construct is capable of being expressed in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant when the construct is integrated, preferably stably integrated, within the caryopsis's or grain's or seedling's or plant's genomic DNA.

7. A construct according to claim 5 or claim 6 wherein the modified Ltp1 gene promoter comprises the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

8. The construct according to any one of claims 5 to 7 wherein the construct further comprises at least one additional sequence to increase expression of the GOI.

9. An expression system for at least the aleurone cells or for at least the scutellar epithelial tissue or vascular tissue of a plant material, the expression system comprising

a GOI fused to a modified Ltp1 gene promoter

wherein the expression system is capable of being expressed in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of the plant material; and

wherein if there is expression in just the aleurone layer of a developing barley caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

10. An expression system according to claim 9 wherein the expression system is for at least the aleurone cells of a developing caryopsis or for at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem).

11. An expression system according to claims 9 or claim 10 wherein the expression system is additionally capable of being expressed in the embryo cells of the germinating grain or the plantlet.

12. An expression system according to any one of claims 9 to 11 wherein the expression system is integrated, preferably stably integrated, within a developing caryopsis's genomic DNA or a germinating seedling's genomic DNA or a developing grain's genomic DNA or a plant's genomic DNA.

13. An expression system according to any one of claims 9 to 12 wherein the gene promoter comprises the sequence shown as SEQ I.D. No. 1 or comprises a sequence that has substantial homology therewith, or is a variant thereof.

14. An expression system for at least the aleurone cells of a developing caryopsis or for at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or developing grain or plant (e.g. in the root, leaves and stem), the expression system comprising

a gene promoter fused to a GOI

wherein the expression system is capable of being expressed in at least the aleurone cells of the developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in

the root, leaves and stem); either

wherein if there is expression in just the aleurone layer of a developing barley caryopsis then either the promoter is not the wild type Ltp1 promoter in its natural enviroment and the GOI is not the Ltp1 functional gene in its natural enviroment; or

wherein if there is expression in just the aleurone layer of a developing caryopsis then the fused promoter and GOI are not the 769 bp fragment of Skriver *et al* (1992).

15. An expression system according to any one of claims 9 to 14 comprising a construct according to any one of claims 5 to 8.

16. A transgenic cereal comprising an expression system according to any one of claims 9 to 15 or a construct according to any one of claims 5 to 8 wherein the expression system or construct is integrated, preferably stably integrated, within the cereal's genomic DNA.

17. The use of a gene promoter as defined in any one of the preceding claims to induce expression of a GOI when fused to the gene promoter in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material.

18. The use according to claim 17 wherein the gene promoter is used to induce expression of a GOI when fused to the gene promoter in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

19. A process of expressing a GOI when fused to a gene promoter as defined in any one of the preceding claims, wherein expression occurs in at least the aleurone cells or in at least the scutellar epithelial tissue or vascular tissue of a plant material.

20. A process according to claim 19 wherein the gene promoter expresses the GOI when fused to the gene promoter in at least the aleurone cells of a developing caryopsis or in at least the scutellar epithelial tissue or vascular tissue of a germinating seedling or a developing grain or a plant (e.g. in the root, leaves and stem).

21. A process according to claim 19 or claim 20 wherein the promoter and GOI are integrated, preferably stably integrated, within a cereal's genomic DNA.

22. A process of expressing in at least the scutellar epithelial tissue or vascular tissue of a developing grain or a germinating seedling or a plant, preferably a developing rice grain or a germinating rice seedling or a transgenic rice plant, an expression system according to any one of claims 9 to 15 or a construct according to any one of claims 5 to 8 wherein the expression system or construct is integrated, preferably stably integrated, within the cereal's genomic DNA.

23. The invention of any one of claims 1 to 22 wherein the gene promoter is a fragment of a barley Ltp1 gene promoter.

24. The invention of claim 23 wherein the promoter is for a 10 kDa lipid transfer protein.

25. The invention of claim 23 or claim 24 wherein the gene promoter is obtainable from plasmid NCIMB 40609.

26. The invention of any one of claims 1 to 15 wherein the gene promoter is used for expression of a GOI in a cereal caryopsis or a cereal grain or a cereal seedling or a cereal plant.

27. The invention of claim 26 wherein the cereal caryopsis is a developing cereal caryopsis, the cereal grain is a developing cereal grain, and the cereal seedling is a germinating cereal seedling.

28. The invention of claim 26 or claim 27 wherein the cereal is any one of a rice, maize, wheat, or barley.

29. The invention of claim 28 wherein the cereal is rice or maize, preferably rice.

30. The invention according to any one of claims 1 to 29 wherein the developing caryopsis is a developing barley caryopsis, the germinating seedling is a germinating rice seedling, the developing grain is a developing rice grain, and the plant is a transgenic rice plant.

31. A combination expression system comprising

a. as a first construct, a construct according to any one of claims 5 to 8; and

b. as a second construct, a construct comprising a GOI and another gene promoter that is tissue- or stage-specific.

32. A combination expression system according to claim 31 wherein each construct is integrated, preferably stably integrated, within a plant material.

33. A combination expression system according to claim 32 wherein each construct is integrated, preferably stably integrated, within a developing caryopsis's genomic DNA or a grain's genomic DNA or a seedling's genomic DNA or a plant's genomic DNA.

34. A combination expression system according to any one of claims 31 to 33 wherein the first construct comprises a modified Ltp1 gene promoter comprising the nucleic acid sequence shown as SEQ. I.D. 1, or a sequence that has substantial homology with that of SEQ. I.D. 1, or a variant thereof.

35. A combination expression system according to any one of claims 31 to 34 wherein the promoter in the second construct is an aleurone specific promoter.

36. A combination expression system according to any one of claims 31 to 35 wherein the promoter in the second construct a barley promoter.

37. A combination expression system according to any one of claims 31 to 35 wherein the second construct is the B22E gene promoter.

38. A combination expression system according to any one of claims 31 to 37 wherein the promoter in the second construct is the Ltp2 gene promoter.

39. A combination expression system according to claim 38 wherein the promoter in the second construct is for a 7 kDa lipid transfer protein.

40. A combination expression system according to claim 38 or 39 wherein the promoter in the second construct is the promoter for Ltp2 of *Hordeum vulgare*.

41. A combination expression system according to any one of claims 31 to 40 wherein the promoter in the second construct comprises the sequence shown as SEQ. I.D. 2, or a sequence that has substantial homology therewith,. or a variant thereof.

42. A combination expression system according to any one of claims 38 to 41 wherein each of the myb site and the myc site in the Ltp2 gene promoter is maintained substantially intact.

43. A combination expression system according to any one of claims 31 to 42 wherein the second construct further comprises at least one additional sequence to increase expression of the GOI.

44. A developing cereal grain, preferably a germinating rice seedling, comprising any one of: a promoter according to any one of claims 1 to 4 or any claim dependent thereon, an expression system according to any one of claims 9 to 15 or any claim dependent thereon, a construct according to any one of claims 5 to 8 or any claim dependent thereon, or a combination expression system according to any one of

claims 31 to 43 or any claim dependent thereon.

45. The invention of any one of the preceding claims wherein each of the myb site and the myc site in the gene promoter is maintained substantially intact.

46. Plasmid NCIMB 40609.

47. A promoter, a construct or an expression system or a combination expression system substantially as described herein with reference to any one of Figures 5 to 9.

(54) Title: POLYUNSATURATED FATTY ACIDS IN PLANTS

(57) Abstract

The present invention relates to compositions and methods for preparing polyunsaturated long chain fatty acids in plants, plant parts and plant cells, such as leaves, roots, fruits and seeds. Nucleic acid sequences and constructs encoding fatty acid desaturases, including Δ5-desaturases, Δ6-desaturases and Δ12-desaturases, are used to generate transgenic plants, plant parts and cells which contain and express one or more transgenes encoding one or more desaturases. Expression of the desaturases with different substrate specificities in the plant system permits the large scale production of polyunsaturated long chain fatty acids such as docosahexaenoic acid, eicosapentaenoic acid, α-linolenic acid, gamma-linolenic acid, arachidonic acid and the like for modification of the fatty acid profile of plants, plant parts and tissues. Manipulation of the fatty acid profiles allows for the production of commercial quantities of novel plant oils and products.

POLYUNSATURATED FATTY ACIDS IN PLANTS

Field of the Invention

This invention relates to modulating levels of enzymes and/or enzyme components capable of altering the production of long chain polyunsaturated fatty acids (PUFAS) in a host plant. The invention is exemplified by the production of PUFAS in plants.

Background

Three main families of polyunsaturated fatty acids (PUFAs) are the 3 fatty acids, exemplified by arachidonic acid, the ω9 fatty acids exemplified by Mead acid, and the ω6 fatty acids, exemplified by eicosapentaenoic acid. PUFAs are important components of the plasma membrane of the cell, where they may be found in such forms as phospholipids. PUFAs also serve as precursors to other molecules of importance in human beings and animals, including the prostacyclins, leukotrienes and prostaglandins. PUFAs are necessary for proper development, particularly in the developing infant brain, and for tissue formation and repair.

Four major long chain PUFAs of importance include docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), which are primarily found in different types of fish oil, gamma-linolenic acid (GLA), which is found in the seeds of a number of plants, including evening primrose (*Oenothera biennis*), borage (*Borago officinalis*) and black currants (*Ribes nigrum*), and stearidonic acid (SDA), which is found in marine oils and plant seeds. Both GLA and another important long chain PUFA, arachidonic acid (ARA), are found in filamentous fungi. ARA can be purified from animal tissues including liver and adrenal gland. Mead acid accumulates in essential fatty acid deficient animals.

For DHA, a number of sources exist for commercial production including a variety of marine organisms, oils obtained from cold water marine fish, and egg yolk fractions. For ARA, microorganisms including the genera *Mortierella, Entomophthora, Phytium* and *Porphyridium* can be used for commercial production. Commercial sources of SDA include the genera *Trichodesma and*

Echium. Commercial sources of GLA include evening primrose, black currants and borage. However, there are several disadvantages associated with commercial production of PUFAs from natural sources. Natural sources of PUFAs, such as animals and plants, tend to have highly heterogeneous oil compositions. The oils obtained from these sources therefore can require extensive purification to separate out one or more desired PUFAs or to produce an oil which is enriched in one or more PUFA. Natural sources also are subject to uncontrollable fluctuations in availability. Fish stocks may undergo natural variation or may be depleted by overfishing. Fish oils have unpleasant tastes and odors, which may be impossible to economically separate from the desired product, and can render such products unacceptable as food supplements. Animal oils, and particularly fish oils, can accumulate environmental pollutants. Weather and disease can cause fluctuation in yields from both fish and plant sources. Cropland available for production of alternate oil-producing crops is subject to competition from the steady expansion of human populations and the associated increased need for food production on the remaining arable land. Crops which do produce PUFAs, such as borage, have not been adapted to commercial growth and may not perform well in monoculture. Growth of such crops is thus not economically competitive where more profitable and better established crops can be grown. Large scale fermentation of organisms such as *Mortierella* is also expensive. Natural animal tissues contain low amounts of ARA and are difficult to process. Microorganisms such as *Porphyridium* and *Mortierella* are difficult to cultivate on a commercial scale.

Dietary supplements and pharmaceutical formulations containing PUFAs can retain the disadvantages of the PUFA source. Supplements such as fish oil capsules can contain low levels of the particular desired component and thus require large dosages. High dosages result in ingestion of high levels of undesired components, including contaminants. Care must be taken in providing fatty acid supplements, as overaddition may result in suppression of endogenous biosynthetic pathways and lead to competition with other necessary fatty acids in various lipid fractions *in vivo*, leading to undesirable results. For example, Eskimos having a diet high in ω3 fatty acids have an increased tendency to bleed (U.S. Pat. No.

4,874,603). Unpleasant tastes and odors of the supplements can make such regimens undesirable, and may inhibit compliance by the patient.

A number of enzymes are involved in PUFA biosynthesis. Linoleic acid (LA, 18:2 Δ9, 12) is produced from oleic acid (18:1 Δ9) by a Δ12-desaturase. GLA (18:3 Δ6, 9, 12) is produced from linoleic acid (LA, 18:2 Δ9, 12) by a Δ6-desaturase. ARA (20:4 Δ5, 8, 11, 14) production from DGLA (20:3 Δ8, 11, 14) is catalyzed by a Δ5-desaturase. However, animals cannot desaturate beyond the Δ9 position and therefore cannot convert oleic acid (18:1 Δ9) into linoleic acid (18:2 Δ9, 12). Likewise, α-linolenic acid (ALA, 18:3 Δ9, 12, 15) cannot be synthesized by mammals. Other eukaryotes, including fungi and plants, have enzymes which desaturate at positions Δ21 and Δ15. The major poly-unsaturated fatty acids of animals therefore are either derived from diet and/or from desaturation and elongation of linoleic acid (18:2 Δ9, 12) or α-linolenic acid (18:3 Δ9, 12, 15).

Poly-unsaturated fatty acids are considered to be useful for nutritional, pharmaceutical, industrial, and other purposes. An expansive supply of poly-unsaturated fatty acids from natural sources and from chemical synthesis are not sufficient for commercial needs. Therefore it is of interest to obtain genetic material involved in PUFA biosynthesis from species that naturally produce these fatty acids and to express the isolated material alone or in combination in a heterologous system which can be manipulated to allow production of commercial quantities of PUFAS.

SUMMARY OF THE INVENTION

Novel compositions and methods are provided for preparation of poly-unsaturated long chain fatty acids and desaturases in plants and plant cells. The methods involve growing a host plant cell of interest transformed with an expression cassette functional in a host plant cell, the expression cassette comprising a transcriptional and translational initiation regulatory region, joined in reading frame 5' to a DNA sequence encoding a desaturase polypeptide capable of modulating the production of PUFAs. Expression of the desaturase polypeptide provides for an alteration in the PUFA profile of host plant cells as a result of

altered concentrations of enzymes involved in PUFA biosynthesis. Of particular interest is the selective control of PUFA production in plant tissues and/or plant parts such as leaves, roots, fruits and seeds. The invention finds use for example in the large scale production of DHA, Mead Acid EPA, ARA, Stearidonic acid and GLA and for modification of the fatty acid profile of edible plant tissues and/or plant parts.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows possible pathways for the synthesis of Mead acid (20:3 Δ5, 8, 11), arachidonic acid (20:4 Δ5, 8, 11, 14) and stearidonic acid (18:4 Δ6, 9, 12, 15) from palmitic acid (C_{16}) from a variety of organisms, including algae, *Mortierella* and humans. These PUFAs can serve as precursors to other molecules important for humans and other animals, including prostacyclins, leukotrienes, and prostaglandins, some of which are shown.

Figure 2 shows possible pathways for production of PUFAs in addition to ARA, including taxoleic acid and pinolenic, again compiled from a variety of organisms.

BRIEF DESCRIPTION OF THE SEQUENCE LISTINGS

SEQ ID NO:1 shows DNA sequence from a *Schizochytrium* clone with homology to both Δ12 and Δ15 desaturases.

SEQ ID NO 2 shows peptide sequence from a *Schizochytrium* clone with homology to both Δ12 and Δ15 desaturases.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to ensure a complete understanding of the invention, the following definitions are provided:

Δ5-Desaturase: Δ5 desaturase is an enzyme which introduces a double bond between carbons 5 and 6 from the carboxyl end of a fatty acid molecule.

Δ6-Desaturase: Δ6-desaturase is an enzyme which introduces a double bond between carbons 6 and 7 from the carboxyl end of a fatty acid molecule.

Δ9-Desaturase: Δ9-desaturase is an enzyme which introduces a double bond between carbons 9 and 10 from the carboxyl end of a fatty acid molecule.

Δ12-Desaturase: Δ12-desaturase is an enzyme which introduces a double bond between carbons 12 and 13 from the carboxyl end of a fatty acid molecule.

Fatty Acids: Fatty acids are a class of compounds containing a long hydrocarbon chain and a terminal carboxylate group. Fatty acids include the following:

Fatty Acid		
12:0	lauric acid	
16:0	Palmitic acid	
16:1	Palmitoleic acid	
18:0	stearic acid	
18:1	oleic acid	Δ9-18:1
18:2 Δ5,9	Taxoleic acid	Δ5,9-18:2
18:2 Δ6,9	6,9-octadecadienoic acid	Δ6,9-18:2
18:2	Linoleic acid	Δ9,12-18:2 (LA)
18:3 Δ6,9,12	Gamma-linolenic acid	Δ6,9,12-18:3 (GLA)
18:3 Δ5,9,12	Pinolenic acid	Δ5,9,12-18:3
18:3	alpha-linolenic acid	Δ9,12,15-18:3 (ALA)
18:4	Stearidonic acid	Δ6,9,12,15-18:4 (SDA)
20:0	Arachidic acid	
20:1	Eicosenic Acid	
20:2 Δ8, 11		Δ8, 11
20:3 Δ5, 8, 11	Mead Acid	Δ5, 8, 11
22:0	Behehic acid	
22:1	erucic acid	
22:2	Docasadienoic acid	
20:4 ω6	arachidonic acid	Δ5,8,11,14-20:4 (ARA)
20:3 ω6	ω6-eicosatrienoic dihomo-gamma linolenic	Δ8,11,14-20:3 (DGLA)
20:5 ω3	Eicosapentanoic (Timnodonic acid)	Δ5,8,11,14,17-20:5 (EPA)
20:3 ω3	ω3-eicosatrienoic	Δ11,16,17-20:3
20:4 ω3	ω3-eicosatetraenoic	Δ8,11,14,17-20:4
22:5 ω3	Docosapentaenoic	Δ7,10,13,16,19-22:5 (ω3DPA)

Fatty Acid		
22:6 ω3	Docosahexaenoic (cervonic acid)	Δ4,7,10,13,16,19-22:6 (DHA)
24:0	Lignoceric acid	

Taking into account these definitions, the present invention is directed to novel DNA sequences, DNA constructs, methods and compositions are provided which permit modification of the poly-unsaturated long chain fatty acid content of plant cells. Plant cells are transformed with an expression cassette comprising a DNA encoding a polypeptide capable of increasing the amount of one or more PUFA in a plant cell. Desirably, integration constructs may be prepared which provide for integration of the expression cassette into the genome of a host cell. Host cells are manipulated to express a sense or antisense DNA encoding a polypeptide(s) that has desaturase activity. By "desaturase" is intended a polypeptide which can desaturate one or more fatty acids to produce a mono- or poly-unsaturated fatty acid or precursor thereof of interest. By "polypeptide" is meant any chain of amino acids, regardless of length or post-translational modification, for example, glycosylation or phosphorylation. The substrate(s) for the expressed enzyme may be produced by the host cell or may be exogenously supplied.

To achieve expression in a host cell, the transformed DNA is operably associated with transcriptional and translational initiation and termination regulatory regions that are functional in the host cell. Constructs comprising the gene to be expressed can provide for integration into the genome of the host cell or can autonomously replicate in the host cell. For production of linoleic acid (LA), the expression cassettes generally used include a cassette which provides for Δ12 desaturase activity, particularly in a host cell which produces or can take up oleic acid. For production of ALA, the expression cassettes generally used include a cassette which provides for Δ15 or ω3 desaturase activity, particularly in a host cell which produces or can take up LA. For production of GLA or SDA, the expression cassettes generally used include a cassette which provides for Δ6 desaturase activity, particularly in a host cell which produces or can take up LA or ALA.

respectively. Production of ω6-type unsaturated fatty acids, such as LA or GLA, is favored in a plant capable of producing ALA by inhibiting the activity of a Δ15 or ω3 type desaturase; this is accomplished by providing an expression cassette for an antisense Δ15 or ω3 transcript, or by disrupting a Δ15 or ω3 desaturase gene. Similarly, production of LA or ALA is favored in a plant having Δ6 desaturase activity by providing an expression cassette for an antisense Δ6 transcript, or by disrupting a Δ6 desaturase gene. Production of oleic acid likewise is favored in a plant having Δ12 desaturase activity by providing an expression cassette for an antisense Δ12 transcript, or by disrupting a Δ12 desaturase gene. For production of ARA, the expression cassette generally used provides for Δ5 desaturase activity, particularly in a host cell which produces or can take up DGLA. Production of ω6-type unsaturated fatty acids, such as ARA, is favored in a plant capable of producing ALA by inhibiting the activity of a Δ15 or ω3 type desaturase; this is accomplished by providing an expression cassette for an antisense Δ15 or ω3 transcript, or by disrupting a Δ15 or ω3 desaturase gene.

TRANSGENIC PLANT PRODUCTION OF FATTY ACIDS

Transgenic plant production of PUFAs offers several advantages over purification from natural sources such as fish or plants. Production of fatty acids from recombinant plants provides the ability to alter the naturally occurring plant fatty acid profile by providing new synthetic pathways in the host or by suppressing undesired pathways, thereby increasing levels of desired PUFAs, or conjugated forms thereof, and decreasing levels of undesired PUFAs. Production of fatty acids in transgenic plants also offers the advantage that expression of desaturase genes in particular tissues and/or plant parts means that greatly increased levels of desired PUFAs in those tissues and/or parts can be achieved, making recovery from those tissues more economical. For example, the desired PUFAs can be expressed in seed; methods of isolating seed oils are well established. In addition to providing a source for purification of desired PUFAs, seed oil components can be manipulated through expression of desaturase genes, either alone or in combination with other genes such as elongases, to provide seed oils having a particular PUFA profile in concentrated form. The concentrated seed oils then can be added to animal milks

and/or synthetic or semi-synthetic milks to serve as infant formulas where human nursing is impossible or undesired, or in cases of malnourishment or disease in both adults and infants.

For production of PUFAs, depending upon the host cell, the availability of substrate, and the desired end product(s), several polypeptides, particularly desaturases, are of interest including those polypeptides which catalyze the conversion of stearic acid to oleic acid, LA to GLA, of ALA to SDA, of oleic acid to LA, or of LA to ALA, which includes enzymes which desaturate at the Δ6, Δ9, Δ12, Δ15 or ω3 positions. Considerations for choosing a specific polypeptide having desaturase activity include the pH optimum of the polypeptide, whether the polypeptide is a rate limiting enzyme or a component thereof, whether the desaturase used is essential for synthesis of a desired poly-unsaturated fatty acid, and/or co-factors required by the polypeptide. The expressed polypeptide preferably has parameters compatible with the biochemical environment of its location in the host cell. For example, the polypeptide may have to compete for substrate with other enzymes in the host cell. Analyses of the K_m and specific activity of the polypeptide in question therefore are considered in determining the suitability of a given polypeptide for modifying PUFA production in a given host cell. The polypeptide used in a particular situation therefore is one which can function under the conditions present in the intended host cell but otherwise can be any polypeptide having desaturase activity which has the desired characteristic of being capable of modifying the relative production of a desired PUFA. A scheme for the synthesis of arachidonic acid (20:4 Δ5, 8, 11, 14) from palmitic acid (C_{16}) is shown in Figure 1. A key enzyme in this pathway is a Δ5-desaturase which converts DH-γ-linolenic acid (DGLA, eicosatrienoic acid) to ARA. Conversion of α-linolenic acid (ALA) to stearidonic acid by a Δ6-desaturase is also shown. Production of PUFAs in addition to ARA, including EPA and DHA is shown in Figure 2. A key enzyme in the synthesis of arachidonic acid (20:4 Δ5, 8, 11, 14) from stearic acid (C_{18}) is a Δ6-desaturase which converts the linoleic acid into γ-linolenic acid. Conversion of α-linolenic acid (ALA) to stearidonic acid by a Δ6-desaturase also is shown. For production of ARA, the DNA sequence used encodes

a polypeptide having Δ5 desaturase activity. In particular instances, this can be coupled with an expression cassette which provides for production of a polypeptide having Δ6 desaturase activity and, optionally, a transcription cassette providing for production of antisense sequences to a Δ 15 transcription product. The choice of combination of cassettes used depends in part on the PUFA profile of the host cell. Where the host cell Δ5-desaturase activity is limiting, overexpression of Δ5 desaturase alone generally will be sufficient to provide for enhanced ARA production.

SOURCES OF POLYPEPTIDES HAVING DESATURASE ACTIVITY

As sources of polypeptides having desaturase activity and oligonucleotides encoding such polypeptides are organisms which produce a desired polyunsaturated fatty acid. As an example, microorganisms having an ability to produce ARA can be used as a source of Δ5-desaturase genes; microorganisms which GLA or SDA can be used as a source of Δ6-desaturase and/or Δ12-desaturase genes. Such microorganisms include, for example, those belonging to the genera *Mortierella*, *Conidiobolus*, *Pythium*, *Phytophathora*, *Penicillium*, *Porphyridium*, *Coidosporium*, *Mucor*, *Fusarium*, *Aspergillus*, *Rhodotorula*, and *Entomophthora*. Within the genus *Porphyridium*, of particular interest is *Porphyridium cruentum*. Within the genus *Mortierella*, of particular interest are *Mortierella elongata*, *Mortierella exigua*, *Mortierella hygrophila*, *Mortierella ramanniana*, var. angulispora, and *Mortierella alpina*. Within the genus *Mucor*, of particular interest are *Mucor circinelloides* and *Mucor javanicus*.

DNAs encoding desired desaturases can be identified in a variety of ways. As an example, a source of the desired desaturase, for example genomic or cDNA libraries from *Mortierella*, is screened with detectable enzymatically- or chemically-synthesized probes, which can be made from DNA, RNA, or non-naturally occurring nucleotides, or mixtures thereof. Probes may be enzymatically synthesized from DNAs of known desaturases for normal or reduced-stringency hybridization methods. Oligonucleotide probes also can be used to screen sources and can be based on sequences of known desaturases, including sequences

conserved among known desaturases, or on peptide sequences obtained from the desired purified protein. Oligonucleotide probes based on amino acid sequences can be degenerate to encompass the degeneracy of the genetic code, or can be biased in favor of the preferred codons of the source organism. Oligonucleotides also can be used as primers for PCR from reverse transcribed mRNA from a known or suspected source; the PCR product can be the full length cDNA or can be used to generate a probe to obtain the desired full length cDNA. Alternatively, a desired protein can be entirely sequenced and total synthesis of a DNA encoding that polypeptide performed.

Once the desired genomic or cDNA has been isolated, it can be sequenced by known methods. It is recognized in the art that such methods are subject to errors, such that multiple sequencing of the same region is routine and is still expected to lead to measurable rates of mistakes in the resulting deduced sequence, particularly in regions having repeated domains, extensive secondary structure, or unusual base compositions, such as regions with high GC base content. When discrepancies arise, resequencing can be done and can employ special methods. Special methods can include altering sequencing conditions by using: different temperatures; different enzymes; proteins which alter the ability of oligonucleotides to form higher order structures; altered nucleotides such as ITP or methylated dGTP; different gel compositions, for example adding formamide; different primers or primers located at different distances from the problem region; or different templates such as single stranded DNAs. Sequencing of mRNA can also be employed.

For the most part, some or all of the coding sequence for the polypeptide having desaturase activity is from a natural source. In some situations, however, it is desirable to modify all or a portion of the codons, for example, to enhance expression, by employing host preferred codons. Host preferred codons can be determined from the codons of highest frequency in the proteins expressed in the largest amount in a particular host species of interest. Thus, the coding sequence for a polypeptide having desaturase activity can be synthesized in whole or in part. All or portions of the DNA also can be synthesized to remove any destabilizing sequences or regions of secondary structure which would be present in the

transcribed mRNA. All or portions of the DNA also can be synthesized to alter the base composition to one more preferable in the desired host cell. Methods for synthesizing sequences and bringing sequences together are well established in the literature. *In vitro* mutagenesis and selection, site-directed mutagenesis, or other means can be employed to obtain mutations of naturally occurring desaturase genes to produce a polypeptide having desaturase activity *in vivo* with more desirable physical and kinetic parameters for function in the host cell, such as a longer half-life or a higher rate of production of a desired polyunsaturated fatty acid.

Desirable cDNAs have less than 60% A+T composition, preferably less than 50% A+T composition. On a localized scale of a sliding window of 20 base pairs, it is preferable that there are no localized regions of the cDNA with greater than 75% A+T composition; with a window of 60 base pairs, it is preferable that there are no localized regions of the cDNA with greater than 60%, more preferably no localized regions with greater than 55% A+T composition.

Mortierella alpina Desaturases

Of particular interest are the *Mortierella alpina* Δ5-desaturase, Δ6-desaturase, Δ12-desaturase and Δ15 desaturase. The gene encoding the *Mortierella alpina* Δ5-desaturase can be expressed in transgenic plants to effect greater synthesis of ARA from DGLA. Other DNAs which are substantially identical in sequence to the *Mortierella alpina* Δ5-desaturase DNA, or which encode polypeptides which are substantially identical in sequence to the *Mortierella alpina* Δ5-desaturase polypeptide, also can be used. The gene encoding the *Mortierella alpina* Δ6-desaturase can be expressed in transgenic plants or animals to effect greater synthesis of GLA from linoleic acid or of stearidonic acid (SDA) from ALA. Other DNAs which are substantially identical in sequence to the *Mortierella alpina* Δ6-desaturase DNA, or which encode polypeptides which are substantially identical in sequence to the *Mortierella alpina* Δ6-desaturase polypeptide, also can be used.

The gene encoding the *Mortierella alpina* Δ12-desaturase can be expressed in transgenic plants to effect greater synthesis of LA from oleic acid. Other DNAs

which are substantially identical to the *Mortierella alpina* Δ12-desaturase DNA, or which encode polypeptides which are substantially identical to the *Mortierella alpina* Δ12-desaturase polypeptide, also can be used.

By substantially identical in sequence is intended an amino acid sequence or nucleic acid sequence exhibiting in order of increasing preference at least 60%, 80%, 90% or 95% homology to the *Mortierella alpina* Δ5-desaturase amino acid sequence or nucleic acid sequence encoding the amino acid sequence. For polypeptides, the length of comparison sequences generally is at least 16 amino acids, preferably at least 20 amino acids, or most preferably 35 amino acids. For nucleic acids, the length of comparison sequences generally is at least 50 nucleotides, preferably at least 60 nucleotides, and more preferably at least 75 nucleotides, and most preferably, 110 nucleotides. Homology typically is measured using sequence analysis software, for example, the Sequence Analysis software package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wisconsin 53705, MEGAlign (DNAStar, Inc., 1228 S. Park St., Madison, Wisconsin 53715), and MacVector (Oxford Molecular Group, 2105 S. Bascom Avenue, Suite 200, Campbell, California 95008). Such software matches similar sequences by assigning degrees of homology to various substitutions, deletions, and other modifications. Conservative substitutions typically include substitutions within the following groups: glycine and alanine; valine, isoleucine and leucine; aspartic acid, glutamic acid, asparagine, and glutamine; serine and threonine; lysine and arginine; and phenylalanine and tyrosine. Substitutions may also be made on the basis of conserved hydrophobicity or hydrophilicity (Kyte and Doolittle, *J. Mol. Biol.* 157: 105-132, 1982), or on the basis of the ability to assume similar polypeptide secondary structure (Chou and Fasman, *Adv. Enzymol.* 47: 45-148, 1978).

EXPRESSION OF DESATURASE GENES

Once the DNA encoding a desaturase polypeptide has been obtained, it is placed in a vector capable of replication in a host cell, or is propagated *in vitro* by means of techniques such as PCR or long PCR. Replicating vectors can include plasmids, phage, viruses, cosmids and the like. Desirable vectors include those

useful for mutagenesis of the gene of interest or for expression of the gene of interest in host cells. The technique of long PCR has made *in vitro* propagation of large constructs possible, so that modifications to the gene of interest, such as mutagenesis or addition of expression signals, and propagation of the resulting constructs can occur entirely *in vitro* without the use of a replicating vector or a host cell.

For expression of a desaturase polypeptide, functional transcriptional and translational initiation and termination regions are operably linked to the DNA encoding the desaturase polypeptide. Transcriptional and translational initiation and termination regions are derived from a variety of nonexclusive sources, including the DNA to be expressed, genes known or suspected to be capable of expression in the desired system, expression vectors, chemical synthesis, or from an endogenous locus in a host cell. Expression in a plant tissue and/or plant part presents certain efficiencies, particularly where the tissue or part is one which is easily harvested, such as seed, leaves, fruits, flowers, roots, etc. Expression can be targeted to that location within the plant by using specific regulatory sequences, such as those of USPN 5,463,174, USPN 4,943,674, USPN 5,106,739, USPN 5,175,095, USPN 5,420,034, USPN 5,188,958, and USPN 5,589,379. Alternatively, the expressed protein can be an enzyme which produces a product which may be incorporated, either directly or upon further modifications, into a fluid fraction from the host plant. In the present case, expression of desaturase genes, or antisense desaturase transcripts, can alter the levels of specific PUFAs, or derivatives thereof, found in plant parts and/or plant tissues. The Δ5-desaturase polypeptide coding region is expressed either by itself or with other genes, in order to produce tissues and/or plant parts containing higher proportions of desired PUFAs or in which the PUFA composition more closely resembles that of human breast milk (Prieto *et al.*, PCT publication WO 95/24494). The termination region can be derived from the 3' region of the gene from which the initiation region was obtained or from a different gene. A large number of termination regions are known to and have been found to be satisfactory in a variety of hosts from the same and different genera and species. The termination region usually is selected more as a matter of convenience rather than because of any particular property.

The choice of a host cell is influenced in part by the desired PUFA profile of the transgenic cell, and the native profile of the host cell. As an example, for production of linoleic acid from oleic acid, the DNA sequence used encodes a polypeptide having Δ12 desaturase activity, and for production of GLA from linoleic acid, the DNA sequence used encodes a polypeptide having Δ6 desaturase activity. Use of a host cell which expresses Δ12 desaturase activity and lacks or is depleted in Δ15 desaturase activity, can be used with an expression cassette which provides for overexpression of Δ6 desaturase alone generally is sufficient to provide for enhanced GLA production in the transgenic cell. Where the host cell expresses Δ9 desaturase activity, expression of both a Δ12- and a Δ6-desaturase can provide for enhanced GLA production. In particular instances where expression of Δ6 desaturase activity is coupled with expression of Δ12 desaturase activity, it is desirable that the host cell naturally have, or be mutated to have, low Δ15 desaturase activity. Alternatively, a host cell for Δ6 desaturase expression may have, or be mutated to have, high Δ12 desaturase activity.

Expression in a host cell can be accomplished in a transient or stable fashion. Transient expression can occur from introduced constructs which contain expression signals functional in the host cell, but which constructs do not replicate and rarely integrate in the host cell, or where the host cell is not proliferating. Transient expression also can be accomplished by inducing the activity of a regulatable promoter operably linked to the gene of interest, although such inducible systems frequently exhibit a low basal level of expression. Stable expression can be achieved by introduction of a construct that can integrate into the host genome or that autonomously replicates in the host cell. Stable expression of the gene of interest can be selected for through the use of a selectable marker located on or transfected with the expression construct, followed by selection for cells expressing the marker. When stable expression results from integration, integration of constructs can occur randomly within the host genome or can be targeted through the use of constructs containing regions of homology with the host genome sufficient to target recombination with the host locus. Where constructs

are targeted to an endogenous locus, all or some of the transcriptional and translational regulatory regions can be provided by the endogenous locus.

When increased expression of the desaturase polypeptide in the source plant is desired, several methods can be employed. Additional genes encoding the desaturase polypeptide can be introduced into the host organism. Expression from the native desaturase locus also can be increased through homologous recombination, for example by inserting a stronger promoter into the host genome to cause increased expression, by removing destabilizing sequences from either the mRNA or the encoded protein by deleting that information from the host genome, or by adding stabilizing sequences to the mRNA (*see* USPN 4,910,141 and USPN 5,500,365.)

When it is desirable to express more than one different gene, appropriate regulatory regions and expression methods, introduced genes can be propagated in the host cell through use of replicating vectors or by integration into the host genome. Where two or more genes are expressed from separate replicating vectors, it is desirable that each vector has a different means of replication. Each introduced construct, whether integrated or not, should have a different means of selection and should lack homology to the other constructs to maintain stable expression and prevent reassortment of elements among constructs. Judicious choices of regulatory regions, selection means and method of propagation of the introduced construct can be experimentally determined so that all introduced genes are expressed at the necessary levels to provide for synthesis of the desired products.

Constructs comprising the gene of interest may be introduced into a host cell by standard techniques. These techniques include transfection, infection, bolistic impact, electroporation, microinjection, scraping, or any other method which introduces the gene of interest into the host cell (*see* USPN 4,743,548, USPN 4,795,855, USPN 5,068,193, USPN 5,188,958, USPN 5,463,174, USPN 5,565,346 and USPN 5,565,347). For convenience, a host cell which has been manipulated by any method to take up a DNA sequence or construct will be referred to as "transformed" or "recombinant" herein. The subject host will have at least have one copy of the expression construct and may have two or more, depending upon

whether the gene is integrated into the genome, amplified, or is present on an extrachromosomal element having multiple copy numbers.

The transformed host cell can be identified by selection for a marker contained on the introduced construct. Alternatively, a separate marker construct may be introduced with the desired construct, as many transformation techniques introduce many DNA molecules into host cells. Typically, transformed hosts are selected for their ability to grow on selective media. Selective media may incorporate an antibiotic or lack a factor necessary for growth of the untransformed host, such as a nutrient or growth factor. An introduced marker gene therefor may confer antibiotic resistance, or encode an essential growth factor or enzyme, and permit growth on selective media when expressed in the transformed host cell. Desirably, resistance to kanamycin and the amino glycoside G418 are of interest (*see* USPN 5,034,322). Selection of a transformed host can also occur when the expressed marker protein can be detected, either directly or indirectly. The marker protein may be expressed alone or as a fusion to another protein. The marker protein can be detected by its enzymatic activity; for example β galactosidase can convert the substrate X-gal to a colored product, and luciferase can convert luciferin to a light-emitting product. The marker protein can be detected by its light-producing or modifying characteristics; for example, the green fluorescent protein of *Aequorea victoria* fluoresces when illuminated with blue light. Antibodies can be used to detect the marker protein or a molecular tag on, for example, a protein of interest. Cells expressing the marker protein or tag can be selected, for example, visually, or by techniques such as FACS or panning using antibodies.

The PUFAs produced using the subject methods and compositions may be found in the host plant tissue and/or plant part as free fatty acids or in conjugated forms such as acylglycerols, phospholipids, sulfolipids or glycolipids, and may be extracted from the host cell through a variety of means well-known in the art. Such means may include extraction with organic solvents, sonication, supercritical fluid extraction using for example carbon dioxide, and physical means such as presses, or combinations thereof. Of particular interest is extraction with hexane or methanol and chloroform. Where desirable, the aqueous layer can be acidified to

protonate negatively charged moieties and thereby increase partitioning of desired products into the organic layer. After extraction, the organic solvents can be removed by evaporation under a stream of nitrogen. When isolated in conjugated forms, the products are enzymatically or chemically cleaved to release the free fatty acid or a less complex conjugate of interest, and are then subjected to further manipulations to produce a desired end product. Desirably, conjugated forms of fatty acids are cleaved with potassium hydroxide.

PURIFICATION OF FATTY ACIDS

If further purification is necessary, standard methods can be employed. Such methods include extraction, treatment with urea, fractional crystallization, HPLC, fractional distillation, silica gel chromatography, high speed centrifugation or distillation, or combinations of these techniques. Protection of reactive groups, such as the acid or alkenyl groups, may be done at any step through known techniques, for example alkylation or iodination. Methods used include methylation of the fatty acids to produce methyl esters. Similarly, protecting groups may be removed at any step. Desirably, purification of fractions containing ARA, DHA and EPA is accomplished by treatment with urea and/or fractional distillation.

USES OF FATTY ACIDS

The uses of the fatty acids of subject invention are several. Probes based on the DNAs of the present invention may find use in methods for isolating related molecules or in methods to detect organisms expressing desaturases. When used as probes, the DNAs or oligonucleotides need to be detectable. This is usually accomplished by attaching a label either at an internal site, for example via incorporation of a modified residue, or at the 5' or 3' terminus. Such labels can be directly detectable, can bind to a secondary molecule that is detectably labeled, or can bind to an unlabelled secondary molecule and a detectably labeled tertiary molecule; this process can be extended as long as is practical to achieve a satisfactorily detectable signal without unacceptable levels of background signal. Secondary, tertiary, or bridging systems can include use of antibodies directed against any other molecule, including labels or other antibodies, or can involve any

molecules which bind to each other, for example a biotin-streptavidin/avidin system. Detectable labels typically include radioactive isotopes, molecules which chemically or enzymatically produce or alter light, enzymes which produce detectable reaction products, magnetic molecules, fluorescent molecules or molecules whose fluorescence or light-emitting characteristics change upon binding. Examples of labelling methods can be found in USPN 5,011,770. Alternatively, the binding of target molecules can be directly detected by measuring the change in heat of solution on binding of probe to target via isothermal titration calorimetry, or by coating the probe or target on a surface and detecting the change in scattering of light from the surface produced by binding of target or probe, respectively, as may be done with the BIAcore system.

The invention will be better understood by reference to the following non-limiting examples.

Examples

Example 1

Expression of ω-3 desaturase from *C. elegans* in transgenic plants.

The D15/ω-3 activity of *Brassica napus* can be increased by the expression of an ω-3 desaturase from *C. elegans*. The fat-1 cDNA clone (Genbank accession L41807; Spychalla, J. P., Kinney, A. J., and Browse, J. 1997 P.N.A.S. 94, 1142-1147 was obtained from John Browse at Washington State University. The fat-1 cDNA was modified by PCR to introduce cloning sites using the following primers:

Fat-1forward:

5'-CUACUACUACUACTGCAGACAATGGTCGCTCATTCCTCAGA-3'

Fat-1reverse:

5'- CAUCAUCAUCAUGCGGCCGCTTACTTGGCCTTTGCCTT - 3'

These primers allowed the amplification of the entire coding region and added PstI and NotI sites to the 5'- and 3'-ends, respectively. The PCR product was subcloned into pAMP1 (GIBCOBRL) using the CloneAmp system (GIBCOBRL)

to create pCGN5562. The sequence was verified by sequencing of both strands to be sure no changes were introduced by PCR. For seed specific expression, the Fat-1 coding region was cut out of pCGN5562 as a PstI/NotI fragment and inserted between the PstI/NotI sites of the binary vector, pCGN8623, to create pCGN5563. PCGN5563 can be introduced into Brassica napus via *Agrobacterium*-mediated transformation.

Construction of pCGN8623

The polylinker region of the napin promoter cassette, pCGN7770, was replaced by ligating the following oligonucleotides:

5'- TCGACCTGCAGGAAGCTTGCGGCCGCGGATCC -3' and

5'- TCGAGGATCCGCGGCCGCAAGCTTCCTGCAGG-3'. These oligonucleotides were ligated into SalI/XhoI-digested pCGN7770 to produce pCGN8619. These oligos encode BamHI, NotI, HindIII, and PstI restriction sites. pCGN8619 contains the oligos oriented such that the PstI site is closest to the napin 5' regulatory region. A fragment containing the napin 5' regulatory region, polylinker, and napin 3' region was removed from pCGN8619 by digestion with Asp718I. The fragment was blunt-ended by filling in the 5' overhangs with Klenow fragment then ligated into pCGN5139 that had been digested with Asp718I and HindIII and blunt-ended by filling in the 5' overhangs with Klenow fragment. A plasmid containing the insert oriented so that the napin promoter was closest to the blunted Asp718I site of pCGN5139 and the napin 3' was closest to the blunted HindIII site was subjected to sequence analysis to confirm both the insert orientation and the integrity of cloning junctions. The resulting plasmid was designated pCGN8623.

To produce high levels of stearidonic acid in *Brassica*, the C. elegans ω-3 desaturase can be combined with D6- and D12-desaturases from *Mortierella alpina*. PCGN5563-transformed plants may be crossed with pCGN5544-transformed plants expressing the D6-and D12-desaturases.

The resulting F1 seeds can be analyzed for stearidonic acid content and selected F1 plants can be used for self-pollination to produce F2 seed, or as donors for production of dihaploids, or additional crosses.

An alternative method to combine the fat-1 cDNA with *M. alpina* D6 and D12 desaturases is to combine them on one T-DNA for transformation. The fat-1 coding region from pCGN5562 can be cut out as a PstI/NotI fragment and inserted into PstI/NotI digested pCGN8619. The transcriptional unit consisting of the napin 5' regulatory region, the fat-1 coding region, and the napin 3'-regulatory region can be cut out as a Sse8387I fragment and inserted into pCGN5544 cut with Sse8387I. The resulting plasmid would contain three napin transcriptional units containing the *C. elegans* ω-3 desaturase, *M. alpina* D6 desaturase, and *M. alpina* D12 desaturase, all oriented in the same direction as the 35S/nptII/tml transcriptional unit used for selection of transformed tissue.

Example 2

Over-Expression of D15-desaturase Activity in Transgenic Canola

The D15-desaturase activity of Brassica napus can be increased by over-expression of the D15-desaturase cDNA clone.

A *B. napus* D15-desaturase cDNA clone was obtained by PCR amplification of first-strand cDNA derived from *B. napus* cv. 212/86. The primers were based on published sequence: Genbank # L01418 Arondel et al. 1992 Science 258:1353-1355.

The following primers were used:

Bnd15-FORWARD

5'-CUACUACUACUAGAGCTCAGCGATGGTTGTTGCTATGGAC-3'

Bnd15-REVERSE

5'-CAUCAUCAUCAUGAATTCTTAATTGATTTTAGATTTG-3'

These primers allowed the amplification of the entire coding region and added SacI and EcoRI sites to the 5'- and 3'-ends, respectively

The PCR product was subcloned into pAMP1 (GIBCOBRL) using the CloneAmp system (GIBCOBRL) to create pCGN5520. The sequence was verified by sequencing of both strands to be sure that the open reading frame remained intact.

For seed specific expression, the D15-desaturase coding region was cut out of pCGN5520 as a BamHI/SalI fragment and inserted between the BglII and XhoI sites of the pCGN7770, to create pCGN5557. The PstI fragment of pCGN5557 containing the napin 5'-regulatory region, *B. napus* D15-desaturase, and napin 3'-regulatory region was inserted into the PstI site of the binary vector, pCGN5138 to produce pCGN5558. pCGN5558 was introduced into *Brassica napus* via *Agrobacterium*-mediated transformation.

To produce high levels of stearidonic acid in *Brassica*, the D15-desaturase can be combined with D6- and D12-desaturases from *Mortierella alpina*. PCGN5558-transformed plants may be crossed with pCGN5544-transformed plants expressing the D6 and D12-desaturases. The resulting F1 seeds can be analyzed for stearidonic acid content and selected F1 plants can be used for self-pollination to produce F2 seed, or as donors for production of dihaploids, or additional crosses.

An alternative method to combine the *B. napus* D15-desaturase with *M. alpina* D6 and D12 desaturases is to combine them on one T-DNA for transformation. The transcription cassette consisting of the napin 5'-regulatory region, the D15-desaturase coding region, and the napin 3'-regulatory region can be cut out of pCGN5557 as a SwaI fragment and inserted into SwaI-digested pCGN5544. The resulting plasmid would contain three napin transcriptional units containing the *M. alpina* D6 desaturase, the *B. napus* D15-desaturase, and the *M. alpina* D12 desaturase, all oriented in the same direction as the 35S/nptII/tml transcriptional unit used for selection of transformed tissue.

Example 3

Expression of Δ5 Desaturase in Plants

Expression in Leaves

Ma29 is a putative *M. alpina* D5 desaturase as determined by sequence homology. This experiment was designed to determine whether leaves expressing Ma29 (as determined by Northern) were able to convert exogenously applied DGLA (20:3) to ARA (20:4).

The Ma29 desaturase cDNA was modified by PCR to introduce convenient restriction sites for cloning. The desaturase coding region has been inserted into a d35 cassette under the control of the double 35S promoter for expression in *Brassica* leaves (pCGN5525) following standard protocols (*see* USPN 5,424,200 and USPN 5,106,739). Transgenic *Brassica* plants containing pCGN5525 were generated following standard protocols (*see* USPN 5,188,958 and USPN 5,463,174).

In the first experiment, three plants were used: a control, LPOO4-1, and two transgenics,, 5525-23 and 5525-29. LP004 is a low-linolenic *Brassica* variety. Leaves of each were selected for one of three treatments: water, GLA or DGLA. GLA and DGLA were purchased as sodium salts from NuChek Prep and dissolved in water at 1 mg/ml. Aliquots were capped under N_2 and stored at -70 degrees C. Leaves were treated by applying a 50 µl drop to the upper surface and gently spreading with a gloved finger to cover the entire surface. Applications were made approximately 30 minutes before the end of the light cycle to minimize any photo-oxidation of the applied fatty acids. After 6 days of treatment one leaf from each treatment was harvested and cut in half through the mid rib. One half was washed with water to attempt to remove unincorporated fatty acid. Leaf samples were lyophilized overnight, and fatty acid composition determined by gas chromatography (GC). The results are shown in Table 1.

Table 1

Fatty Acid Analysis of Leaves from Ma29 Transgenic *Brassica* Plants

Leaves treated with GLA contained from 1.56 to 2.4 wt% GLA. The fatty acid analysis showed that the lipid composition of control and transgenic leaves was essentially the same. Leaves of control plants treated with DGLA contained 1.2-1.9 w% DGLA and background amounts of ARA (.26-.27 wt%). Transgenic leaves contained only .2-.7 wt% DGLA, but levels of ARA were increased (.74-1.1 wt%) indicating that the DGLA was converted to ARA in these leaves.

Expression in Seed

The purpose of this experiment was to determine whether a construct with the seed specific napin promoter would enable expression in seed.

The Ma29 cDNA was modified by PCR to introduce *Xho*I cloning sites upstream and downstream of the start and stop codons, respectively, using the following primers:

Madxho-forward:

5'-CUACUACUACUACTCGAGCAAGATGGGAACGGACCAAGG

Madxho-reverse:

5'-CAUCAUCAUCAUCTCGAGCTACTCTTCCTTGGGACGGAG

The PCR product was subcloned into pAMP1 (GIBCOBRL) using the CloneAmp system (GIBCOBRL) to create pCGN5522 and the Δ5 desaturase sequence was verified by sequencing of both strands.

For seed-specific expression, the Ma29 coding region was cut out of pCGN5522 as an *Xho*I fragment and inserted into the *Sal*I site of the napin expression cassette, pCGN3223, to create pCGN5528. The *Hin*dIII fragment of pCGN5528 containing the napin 5' regulatory region, the Ma29 coding region, and the napin 3' regulatory region was inserted into the *Hin*dIII site of pCGN1557 to create pCGN5531. Two copies of the napin transcriptional unit were inserted in tandem. This tandem construct can permit higher expression of the desaturases per genetic loci. pCGN5531 was introduced into *Brassica napus* cv.LP004 via Agrobacterium mediated transformation.

The fatty acid composition of twenty-seed pools of mature T2 seeds was analyzed by GC. Table 2 shows the results obtained with independent transformed lin s as compared to non-transform d LP004 seed. The transgenic seeds containing

pCGN5531 contain two fatty acids that are not present in the control seeds, tentatively identified as taxoleic acid (5,9-18:2) and pinolenic acid (5,9,12-18:3), based on their elution relative to oleic and linoleic acid. These would be the expected products of Δ5 desaturation of oleic and linoleic acids. No other differences in fatty acid composition were observed in the transgenic seeds.

Example 4

Production of D5-desaturated Fatty Acids in Transgenic Plants

The construction of pCGN5531 (D5-desaturase) and fatty acid composition of T2 seed pools is described in Example 3. This example takes the seeds through one more generation and discusses ways to maximize the D5-desaturated fatty acids.

Example 3 describes the fatty acid composition of T2 seed pools of pCGN5531-transformed *B. napus* cv. LP004 plants. To investigate the segregation of D5-desaturated fatty acids in the T2 seeds and to identify individual plants to be taken on to subsequent generations, half-seed analysis was done. Seeds were germinated overnight in the dark at 30 degrees on water-soaked filter paper. The outer cotyledon was excised for GC analysis and the rest of the seedling was planted in soil. Results of some of these analyses are shown in the accompanying Table 3. D5,9-18:2 accumulated to as high as 12% of the total fatty acids and D5,9,12-18:3 accumulated to up to 0.77% of the fatty acids. These and other individually selected T2 plants were grown in the greenhouse to produce T3 seed.

To maximize the accumulation of D5,9 18:2 in seed oil, the pCGN5531 construct could be introduced into a high oleic acid variety of canola. A high-oleic variety could be obtained by mutation, so-suppression, or antisense suppression of the D12 and D15 desaturases or other necessary co-factors.

To maximize accumulation of D5,9,12 18:3 in canola, the pCGN5531 construct could be introduced into a high linoleic strain of canola. This could be achieved by crossing pCGN5531-transformed plants with pCGN5542-(M. alpina D12-desaturase) transformed plants. Alternatively, the D5 and D12 desaturases could be combined on one T-DNA for transformation. The transcriptional unit consisting of the napin 5'-regulatory region, the *M. alpina* D12-desaturase coding region, and the napin 3'-regulatory region can be cut out of pCGN5541 (described in CGAB320) as a NotI fragment. NotI/XbaI linkers could be ligated and the resulting fragment insdrted into the XbaI site of pCGN5531. The resulting plasmid would contain three napin transcriptional units containing the *M. alpina* D12 desaturase, and two copies of the napin/*M. alphina* D5 desaturase/napin unit, all oriented in the same direction as the 35S/nptII/tml transcriptional unit used for selection of transformed tissue.

Example 5

Expression of *M. alpina* Δ6 Desaturase in *Brassica napus*

A nucleic acid sequence from a partial cDNA clone, Ma524, encoding a Δ6 fatty acid desaturase from *Mortierella alpina* was obtained by random sequencing of clones from the *M. alpina* cDNA library. The Ma524 cDNA was modified by PCR to introduce cloning sites using the following primers:

Ma524PCR-1

5'-CUACUACUACUATCTAGACTCGAGACCATGGCTGCTGCT
CCAGTGTG

Ma524PCR-2

5'-CAUCAUCAUCAUAGGCCTCGAGTTACTGCGCCTTACCCAT

These primers allowed the amplification of the entire coding region and added *XbaI* and *XhoI* sites to the 5'-end and *XhoI* and *StuI* sites to the 3' end. The PCR product was subcloned into pAMP1 (GIBCOBRL) using the CloneAmp system (GIBCOBRL) to create pCGN5535 and the Δ6 desaturase sequence was verified by sequencing of both strands.

For seed-specific expression, the Ma524 coding region was cut out of pCGN5535 as an *XhoI* fragment and inserted into the *SalI* site of the napin expression cassette, pCGN3223, to create pCGN5536. The *NotI* fragment of pCGN5536 containing the napin 5' regulatory region, the Ma524 coding region, and the napin 3' regulatory region was inserted into the *NotI* site of pCGN1557 to create pCGN5538. pCGN5538 was introduced into *Brassica napus* cv.LP004 via *Agrobacterium* mediated transformation.

Maturing T2 seeds were collected from 6 independent transformation events in the greenhouse. The fatty acid composition of single seeds was analyzed by GC. Table 4 shows the results of control LP004 seeds and six 5538 lines. All of the 5538 lines except #8 produced seeds containing GLA. Presence of GLA segregated in these seeds as is expected for the T2 selfed seed population. In addition to GLA, the *M. alpina* Δ6 desaturase is capable of producing 18:4 (stearidonic) and another fatty acid believed to be the 6,9-18:2.

The above results show that desaturases with three different substrate specificities can be expressed in a heterologous system and used to produce poly-unsaturated long chain fatty acids. Exemplified were the production of ARA (20:4) from the precursor 20:3 (DGLA), the production of GLA (18:3) from 18:2 substrate, and the conversion of 18:1 substrate to 18:2, which is the precursor for GLA.

Example 6

Production of D6,9 18:2 in Canola Oil

Example 5 described construction of pCGN5538 designed to express the ***M. alpina*** D6 desaturase in seeds of transgenic canola. Table 4 in that example showed examples of single seed analyses from 6 independent transgenic events. Significant amounts of GLA were produced, in addition to the D6,9 18:2 fatty acid.

A total of 29 independent pCGN5538-transformed transgenic plants of the low-linolenic LP004 cultivar were regenerated and grown in the greenhouse. Table 5 shows the fatty acid composition of 20-seed pools of T2 seed from each event. Seven of the lines contained more than 2% of the D6,9 18:2 in the seed pools. To identify and select plants with high amounts of D6,9 18:2 to be taken on to subsequent generations, half-seed analysis was done. Seeds were germinated overnight in the dark at 30 degrees on water-soaked filter paper. The outer cotyledon was excised for GC analysis and the rest of the seedling was planted in soil. Based on results of fatty acid analysis, selected T2 plants were grown in the greenhouse to produce T3 seed. The selection cycle was repeated; pools of T3 seed were analyzed for D6,9 18:2, T3 half-seeds were dissected and analyzed, and selected T3 plants were grown in the greenhouse to produce T4 seed. Pools of T4 seed were analyzed for fatty acid composition. Table 5 summarizes the results of this process for lines derived from one of the original transgenic events, 5538-LP004-25. Levels of D6,9 18:2 have thus been maintained through 3 generations.

To maximize the amount of D6,9 18:2 that could be produced, the pCGN5538 construct could be introduced into a high oleic acid variety of canola either by transformation or crossing. A high-oleic variety could be obtained by mutation, co-suppression, or antisense suppression of the D12 and D15 desaturases or other necessary co-factors.

Example 7

Identification of potentially useful D15/ω-3 desaturases from other organisms

To look for desaturases involved in PUFA production, cDNA libraries were constructed from total RNA isolated from *Schizochytrium* (unknown species - proprietary strain supplied by Kelco in San Diego). Plasmid-based cDNA libraries were constructed in pSPORT1 (GIBCO-BRL) following manufacturer's instructions using a commercially available kit (GIBCO-BRL). Random cDNA clones were sequenced and nucleic acid sequences that encode putative desaturases were identified through BLAST search of the databases and comparison to known D12 and D15 sequences.

One clone was identified from the *Schizochytrium* library with homology to both D12 and D15 desaturases; it is called 81-53-A2. The DNA Sequence is presented as Seq ID NO:1. The corresponding peptide sequence is presented as SEQ ID NO: 2

CLAIMS:

1. A method of producing a polyunsaturated fatty acid in a host cell comprising the steps of:
   (A) transforming a host cell with a nucleotide sequence comprising: 1) an expression cassette comprising a transcriptional and translational initiation regulatory region, said expression cassette being joined in reading frame 5' to 2) a DNA sequence encoding a desaturase polypeptide which modulates the production of polyunsaturated fatty acids; and
   (B) culturing said transformed host cell under time and conditions sufficient for the expression of said desaturase polypeptide in said host cell, expression of said desaturase polypeptide resulting in production of polyunsaturated fatty acids by said host cell.

(54) Title: PLANT FATTY ACID SYNTHASES AND USE IN IMPROVED METHODS FOR PRODUCTION OF MEDIUM–CHAIN FATTY ACIDS

(57) Abstract

By this invention, compositions and methods of use related to β–ketoacyl–ACP synthase of special interest are synthases obtainable from *Cuphea* species. Amino acid and nucleic acid for synthase protein factors are provided, as well as methods to utilize such sequences in constructs for production of genetically engineered plants having altered fatty acid compositions. Of particular interest is the expression of synthase protein factors in conjunction with expression of plant medium–chain acyl–ACP thioesterases for production of increased levels and/or modified ratios of medium–chain fatty acids in oils of transgenic plant seeds.

PLANT FATTY ACID SYNTHASES AND USE IN IMPROVED METHODS FOR PRODUCTION OF MEDIUM-CHAIN FATTY ACIDS

INTRODUCTION

Field of Invention

The present invention is directed to genes encoding plant fatty acid synthase enzymes relevant to fatty acid synthesis in plants, and to methods of using such genes in combination with genes encoding plant medium-chain preferring thioesterase proteins. Such uses provide a method to increase the levels of medium-chain fatty acids that may be produced in seed oils of transgenic plants.

Background

Higher plants synthesize fatty acids via a common metabolic pathway. In developing seeds, where fatty acids attached to triglycerides are stored as a source of energy for further germination, the fatty acid synthesis pathway is located in the plastids. The first step is the formation of acetyl-ACP (acyl carrier protein) from acetyl-CoA and ACP catalyzed by a short chain preferring condensing enzyme, ß-ketoacyl-ACP synthase (KAS) III. Elongation of acetyl-ACP to 16- and 18- carbon fatty acids involves the cyclical action of the following sequence of reactions: condensation with a two-carbon unit from malonyl-ACP to form a longer ß-ketoacyl-ACP (ß-ketoacyl-ACP synthase), reduction of the

keto-function to an alcohol (ß-ketoacyl-ACP reductase), dehydration to form an enoyl-ACP (ß-hydroxyacyl-ACP dehydrase), and finally reduction of the enoyl-ACP to form the elongated saturated acyl-ACP (enoyl-ACP reductase). ß-ketoacyl-ACP synthase I (KAS I), is primarily responsible for elongation up to palmitoyl-ACP (C16:0), whereas ß-ketoacyl-ACP synthase II (KAS II) is predominantly responsible for the final elongation to stearoyl-ACP (C18:0).

Genes encoding peptide components of ß-ketoacyl-ACP synthases I and II have been cloned from a number of higher plant species, including castor (*Ricinus communis*) and *Brassica* species (USPN 5,510,255). KAS I activity was associated with a single synthase protein factor having an approximate molecular weight of 50 kD (synthase factor B) and KAS II activity was associated with a combination of two synthase protein factors, the 50 kD synthase factor B and a 46 kd protein designated synthase factor A. Cloning and sequence of a plant gene encoding a KAS III protein has been reported by Tai and Jaworski (*Plant Physiol.* (1993) *103*:1361-1367).

The end products of plant fatty acid synthetase activities are usually 16- and 18-carbon fatty acids. There are, however, several plant families that store large amounts of 8- to 14-carbon (medium-chain) fatty acids in their oilseeds. Recent studies with *Umbellularia californica* (California bay), a plant that produces seed oil rich in lauric acid (12:0), have demonstrated the existence of a medium-chain-specific isozyme of acyl-ACP thioesterase

in the seed plastids. Subsequent purification of the 12:0-ACP thioesterase from *Umbellularia californica* led to the cloning of a thioesterase cDNA which was expressed in seeds of *Arabidopsis* and *Brassica* resulting in a substantial accumulation of lauric acid in the triglyceride pools of these transgenic seeds (USPN 5,512,482). These results and subsequent studies with medium-chain thioesterases from other plant species have confirmed the chain-length-determining role of acyl-ACP thioesterases during de novo fatty acid biosynthesis (T. Voelker (1996) *Genetic Engineering*, Ed. J. K. Setlow, Vol. 18, pgs. 111-133).

SUMMARY OF THE INVENTION

By this invention, compositions and methods of use related to ß-ketoacyl-ACP synthase (KAS) are provided. Also of interest are methods and compositions of amino acid and nucleic acid sequences related to biologically active plant synthase(s).

In particular, genes encoding KAS protein factors A and B from *Cuphea* species are provided. The KAS genes are of interest for use in a variety of applications, and may be

used to provide synthase I and/or synthase II activities in transformed host cells, including bacterial cells, such as *E. coli*, and plant cells. Synthase activities are distinguished by the preferential activity towards longer and shorter acyl-ACPs as well as by the sensitivity towards the KAS specific inhibitor, cerulenin. Synthase protein preparations having preferential activity towards medium chain length acyl-ACPs are synthase I-type or KAS I. The KAS I class is sensitive to inhibition by cerulenin at concentrations as low as 1μM. Synthases having preferential activity towards longer chain length acyl-ACPs are synthase II-type or KAS II. The KAS enzymes of the II-type are also sensitive to cerulenin, but at higher concentrations (50μM). Synthase III-type enzymes have preferential activity towards short chain length acyl-ACPs and are insensitive to cerulenin inhibition.

Nucleic acid sequences encoding a synthase protein may be employed in nucleic acid constructs to modulate the amount of synthase activity present in the host cell, especially the relative amounts of synthase I-type, synthase II-type and synthase III-type activity when the host cell is a plant host cell. In addition, nucleic acid constructs may be designed to decrease expression of endogenous synthase in a plant cell as well. One example is the use of an anti-sense synthase sequence under the control of a promoter capable of expression in at least those plant cells which normally produce the enzyme.

Of particular interest in the present invention is the coordinate expression of a synthase protein with the

expression of thioesterase proteins. For example, coordinated expression of synthase factor A and a medium-chain thioesterase provides a method for increasing the level of medium-chain fatty acids which may be harvested from transgenic plant seeds. Furthermore, coordinated expression of a synthase factor A gene with plant medium-chain thioesterase proteins also provides a method by which the ratios of various medium-chain fatty acids produced in a transgenic plant may be modified. For example, by expression of a synthase factor A, it is possible to increase the ratio of C10/C8 fatty acids which are produced in plant seed oils as the result of expression of a thioesterase having activity on C8 and C10 fatty acids.

DETAILED DESCRIPTION OF THE INVENTION

A plant synthase factor protein of this invention includes a sequence of amino acids or polypeptide which is required for catalyzation of a condensation reaction between an acyl-ACP having a chain length of C_2 to C_{16} and malonyl-ACP in a plant host cell. A particular plant synthase factor protein may be capable of catalyzing a synthase reaction in a plant host cell (for example as a monomer or homodimer) or may be one component of a multiple peptide enzyme which is capable of catalyzing a synthase reaction in a plant host cell, i.e. one peptide of a heterodimer.

Synthase I (KAS I) demonstrates preferential activity towards acyl-ACPs having shorter carbon chains, C_2-C_{14} and is sensitive to inhibition by cerulenin at concentrations of 1μM. Synthase II (KAS II) demonstrates preferential

activity towards acyl-ACPs having longer carbon chains, C_{14}-C_{16}, and is inhibited by concentrations of cerulenin (50µM). Synthase III demonstrates preferential activity towards acyl-CoAs having very short carbon chains, C_2 to C_6, and is insensitive to inhibition by cerulenin.

Synthase factors A and B, and synthase III proteins obtained from medium-chain fatty acid producing plant species of the genus *Cuphea* are described herein. As described in the following Examples, synthase A from *C. hookeriana* is naturally expressed at a high level and only in the seeds. *C. hookeriana* synthase B is expressed at low levels in all tissues examined. Expression of synthase A and synthase B factors in *E. coli* and purification of the resulting proteins is employed to determine activity of the various synthase factors. Results of these analyses indicate that synthase factor A from *Cuphea hookeriana* has the greatest activity on 6:0-ACP substrates, whereas synthase factor B from *Cuphea pullcherrima* has greatest activity on 14:0-ACP. Similar studies with synthase factors A and B from castor demonstrate similar activity profiles between the factor B synthase proteins from *Cuphea* and castor. The synthase A clone from castor, however, demonstrates a preference for 14:0-ACP substrate.

Expression of a *Cuphea hookeriana* KAS A protein in transgenic plant seeds which normally do not produce medium-chain fatty acids does not result in any detectable modification of the fatty acid types and contents produced in such seeds. However, when *Cuphea hookeriana* KAS A protein is expressed in conjunction with expression of a

medium-chain acyl-ACP thioesterase capable of providing for production of C8 and C10 fatty acids in plant seed oils, increases in the levels of medium-chain fatty acids over the levels obtainable by expression of the medium-chain thioesterase alone are observed. In addition, where significant amounts of C8 and C10 fatty acids are produced as the result of medium-chain thioesterase expression, co-expression of a *Cuphea* KAS A protein also results in an alteration of the proportion of the C8 and C10 fatty acids that are obtained. For example, an increased proportion of C10 fatty acids may be obtained by co-expression of *Cuphea hookeriana* ChFatB2 thioesterase and a chKAS A synthase factor proteins.

Furthermore, when *Cuphea hookeriana* KAS A protein is expressed in conjunction with expression of a medium-chain acyl-ACP thioesterase capable of providing for production of C12 fatty acids in plant seed oils, increases in the levels of medium-chain fatty acids over the levels obtainable by expression of the medium-chain thioesterase alone are also observed. In addition, where significant amounts of C12 and C14 fatty acids are produced as the result of medium-chain thioesterase expression, co-expression of a *Cuphea* KAS A protein also results in an alteration of the proportion of the C12 and C14 fatty acids that are obtained. For example, an increased proportion of C12 fatty acids may be obtained by co-expression of *Uc* FatB1 thioesterase and a chKAS A synthase factor proteins.

However, when *Cuphea hookeriana* KAS A protein is expressed in conjunction with the expression of a long-chain

acyl-ACP thioesterase capable of providing for production of C18 and C18:1 fatty acids in plant seed oils, no effect on the production of long chain fatty acids was observed. Furthermore, when plants transformed to express a long chain acyl-ACP thioesterase from mangosteen (*Garm*FatA1, U.S. Patent Application No. 08/440,845), which preferentially hydrolyzes C18:0 and C18:1 fatty acyl-ACPs, are crossed with nontransformed control plants, a significant reduction in the levels of C18:0 is obtained. Similar reductions are also observed in the levels of C18:0 in the seeds of plants resulting from crosses between plants transformed to express the *Garm*FatA1 and plants expressing the *Cuphea hookeriana* KAS A protein.

Thus, the instant invention provides methods of increasing and/or altering the medium-chain fatty acid compositions in transgenic plant seed oils by co-expression of medium-chain acyl-ACP thioesterases with synthase factor proteins. Furthermore, various combinations of synthase factors and medium-chain thioesterases may be achieved depending upon the particular fatty acids desired. For example, for increased production of C14 fatty acids, synthase protein factors may be expressed in combination with a C14 thioesterase, for example from *Cuphea palustris* or nutmeg may be employed (WO 96/23892). In addition, thioesterase expression may be combined with a number of different synthase factor proteins for additional effects on medium-chain fatty acid composition.

Synthases of use in the present invention include modified amino acid sequences, such as sequences which have

been mutated, truncated, increased and the like, as well as such sequences which are partially or wholly artificially synthesized. The synthase protein encoding sequences provided herein may be employed in probes for further screening or used in genetic engineering constructs for transcription or transcription and translation in host cells, especially plant host cells. One skilled in the art will readily recognize that antibody preparations, nucleic acid probes (DNA and RNA) and the like may be prepared and used to screen and recover synthases and/or synthase nucleic acid sequences from other sources. Typically, a homologously related nucleic acid sequence will show at least about 60% homology, and more preferably at least about 70% homology, between the *R. communis* synthase and the given plant synthase of interest, excluding any deletions which may be present. Homology is determined upon comparison of sequence information, nucleic acid or amino acid, or through hybridization reactions.

Recombinant constructs containing a nucleic acid sequence encoding a synthase protein factor or nucleic acid sequences encoding a synthase protein factor and a medium-chain acyl-ACP thioesterase may be prepared by methods well known in the art. Constructs may be designed to produce synthase in either prokaryotic or eukaryotic cells. The increased expression of a synthase in a plant cell, particularly in conjunction with expression of medium-chain thioesterases, or decreasing the amount of endogenous synthase observed in plant cells are of special interest.

Synthase protein factors may be used, alone or in combination, to catalyze the elongating condensation reactions of fatty acid synthesis depending upon the desired result. For example, rate influencing synthase activity may reside in synthase I-type, synthase II-type, synthase III-type or in a combination of these enzymes. Furthermore, synthase activities may rely on a combination of the various synthase factors described herein.

Constructs which contain elements to provide the transcription and translation of a nucleic acid sequence of interest in a host cell are "expression cassettes". Depending upon the host, the regulatory regions will vary, including regions from structural genes from viruses, plasmid or chromosomal genes, or the like. For expression in prokaryotic or eukaryotic microorganisms, particularly unicellular hosts, a wide variety of constitutive or regulatable promoters may be employed. Among transcriptional initiation regions which have been described are regions from bacterial and yeast hosts, such as *E. coli, B. subtilis, Saccharomyces cerevisiae*, including genes such as ß-galactosidase, T7 polymerase, trp-lac (tac), trp E and the like.

An expression cassette for expression of synthase in a plant cell will include, in the 5' to 3' direction of transcription, a transcription and translation initiation control regulatory region (also known as a "promoter") functional in a plant cell, a nucleic acid sequence encoding a synthase, and a transcription termination region. Numerous transcription initiation regions are available

which provide for a wide variety of constitutive or regulatable, e.g., inducible, transcription of the desaturase structural gene. Among transcriptional initiation regions used for plants are such regions associated with cauliflower mosaic viruses (35S, 19S), and structural genes such as for nopaline synthase or mannopine synthase or napin and ACP promoters, etc. The transcription/ translation initiation regions corresponding to such structural genes are found immediately 5' upstream to the respective start codons. Thus, depending upon the intended use, different promoters may be desired.

Of special interest in this invention are the use of promoters which are capable of preferentially expressing the synthase in seed tissue, in particular, at early stages of seed oil formation. Examples of such seed-specific promoters include the region immediately 5' upstream of a napin or seed ACP genes such as described in USPN 5,420,034, desaturase genes such as described in Thompson *et al* (*Proc. Nat. Acad. Sci.* (1991) *88:2578-2582)*, or a Bce-4 gene such as described in USPN 5,530,194. Alternatively, the use of the 5' regulatory region associated with the plant synthase structural gene, i.e., the region immediately 5' upstream to a plant synthase structural gene and/or the transcription termination regions found immediately 3' downstream to the plant synthase structural gene, may often be desired. In general, promoters will be selected based upon their expression profile which may change given the particular application.

In addition, one may choose to provide for the transcription or transcription and translation of one or more other sequences of interest in concert with the expression or anti-sense of the synthase sequence, particularly medium-chain plant thioesterases such as described in USPN 5,512,482, to affect alterations in the amounts and/or composition of plant oils.

When one wishes to provide a plant transformed for the combined effect of more than one nucleic acid sequence of interest, a separate nucleic acid construct may be provided for each or the constructs may both be present on the same plant transformation construct. The constructs may be introduced into the host cells by the same or different methods, including the introduction of such a trait by crossing transgenic plants via traditional plant breeding methods, so long as the resulting product is a plant having both characteristics integrated into its genome.

Normally, included with the DNA construct will be a structural gene having the necessary regulatory regions for expression in a host and providing for selection of transformed cells. The gene may provide for resistance to a cytotoxic agent, e.g. antibiotic, heavy metal, toxin, etc., complementation providing prototrophy to an auxotrophic host, viral immunity or the like. Depending upon the number of different host species into which the expression construct or components thereof are introduced, one or more markers may be employed, where different conditions for selection are used for the different hosts.

The manner in which the DNA construct is introduced into the plant host is not critical to this invention. Any method which provides for efficient transformation may be employed. Various methods for plant cell transformation include the use of Ti- or Ri-plasmids, microinjection, electroporation, liposome fusion, DNA bombardment or the like. In many instances, it will be desirable to have the construct bordered on one or both sides by T-DNA, particularly having the left and right borders, more particularly the right border. This is particularly useful when the construct uses *A. tumefaciens* or *A. rhizogenes* as a mode for transformation, although the T-DNA borders may find use with other modes of transformation.

The expression constructs may be employed with a wide variety of plant life, particularly plant life involved in the production of vegetable oils. These plants include, but are not limited to rapeseed, peanut, sunflower, safflower, cotton, soybean, corn and oilseed palm.

For transformation of plant cells using *Agrobacterium*, explants may be combined and incubated with the transformed *Agrobacterium* for sufficient time for transformation, the bacteria killed, and the plant cells cultured in an appropriate selective medium. Once callus forms, shoot formation can be encouraged by employing the appropriate plant hormones in accordance with known methods and the shoots transferred to rooting medium for regeneration of plants. The plants may then be grown to seed and the seed used to establish repetitive generations and for isolation of vegetable oils.

The invention now being generally described, it will be more readily understood by reference to the following examples which are included for purposes of illustration only and are not intended to limit the present invention.

EXAMPLES

Example 1 Cuphea KAS Factor A and B Gene Cloning

Total RNA isolated from developing seeds of *Cuphea hookeriana* and *Cuphea pullcherrima* was used for cDNA synthesis in commercial l-based cloning vectors. For cloning each type of KAS gene, approximately 400,000-500,000 unamplified recombinant phage were plated and the plaques transferred to nitrocellulose. For KAS factor B cloning from *C. hookeriana*, a mixed probe containing *Brassica napus* KAS factor B and *Ricinus communis* (Castor) KAS factor B radiolabeled cDNA's was used. Similarly, a mixed probe containing *Brassica napus* KAS factor A and *Ricinus communis* KAS factor A cDNA clones was used to obtain *C. hookeriana* KAS factor A genes. For KASIII, a spinach KASIII cDNA clone obtained from Dr. Jan Jaworski was radiolabeled and used as a probe to isolate a KASIII clone from *C. hookeriana*. For KAS B and KAS A cloning from *C. pullcherrima*, *C. hookeriana* KAS B and KAS A genes chKAS B-2 and chKAS A-2-7 (see below) were radiolabeled and used as probes.

DNA sequence and translated amino acid sequence for *Cuphea* KAS clones are provided in Figures 1-9. *Cuphea hookeriana* KAS factor B clones chKAS B-2 and chKAS B-31-7

are provided in Figures 1 and 2. Neither of the clones is full length. *Cuphea hookeriana* KAS Factor A clones chKAS A-2-7 and chKAS A-1-6 are provided in Figures 3 and 4. chKAS A-2-7 contains the entire encoding sequence for the KAS factor protein. Based on comparison with other plant synthase proteins, the transit peptide is believed to be represented in the amino acids encoded by nucleotides 125-466. chKAS A-1-6 is not a full length clone although some transit peptide encoding sequence is present. Nucleotides 1-180 represent transit peptide encoding sequence, and the mature protein encoding sequence is believed to begin at nucleotide 181.

Cuphea pullcherrima KAS factor B clones cpuKAS B/7-8 and cpuKAS B/8-7A are provided in Figures 5 and 6. Both of the clones contain the entire encoding sequences for the KAS factor B proteins. The first 35 amino acids of cpuKAS B/7-8 are believed to represent the transit peptide, with the mature protein encoding sequence beginning at nucleotide 233. The first 39 amino acids of cpuKAS B/8-7A are believed to represent the transit peptide, with the mature protein encoding sequence beginning at nucleotide 209. *Cuphea pullcherrima* KAS factor A clones cpuKAS A/p7-6A and cpuKAS A-p8-9A are provided in Figures 7 and 8. Both of the clones contain the entire encoding sequences for the KAS factor A proteins. Translated amino acid sequence of cpuKAS A/p7-6A is provided. The mature protein is believed to begin at the lysine residue encoded 595-597, and the first 126 amino acids are believed to represent the transit peptide. The DNA sequence of KAS A clone cpuKAS A-p8-9A is preliminary.

Further analysis will be conducted to determine final DNA sequence and reveal the amino acid sequence encoded by this gene.

DNA and translated amino acid sequence of *Cuphea hookeriana* KASIII clone chKASIII-27 is provided in Figure 9. The encoding sequence from nucleotides 37-144 of chKASIII-27 are believed to encode a transit peptide, and the presumed mature protein encoding sequence is from nucleotides 145-1233.

Deduced amino acid sequence of the *C. hookeriana* KAS factor B and KAS factor A cDNA's reveals strong homology to the *Brassica napus* and *Ricinus communis* clones previously reported. The *C. hookeriana* KAS factor B clone is more homologous to the *Ricinus* and *Brassica* KAS factor B clones (94% and 91% respectively) than it is to the *Ricinus* and *Brassica* KAS factor A clones (60% for both). Furthermore, the *C. hookeriana* KAS factor A clone is more homologous to the *Ricinus* and *Brassica* KAS factor A clones (85% and 82% respectively) than it is the *Ricinus* and *Brassica* KAS factor B clone (60% for both). The *C. hookeriana* KAS factor B cDNAs designated as chKAS B-2 and chKAS B-31-7 are 96% identical within the mature portion of the polypeptide. Similarly, the deduced amino acid sequence of the mature protein regions of the *C. hookeriana* KAS factor A clones chKAS A-2-7 and chKAS A-1-6 are 96% identical. The *C. pullcherrima* KAS clones also demonstrate homology to the *R. communis* and *Brassica napus* KAS clones. The mature protein portion of all of the KAS factor A family members in the different *Cuphea* species are 95% identical. Similarly the

mature protein portion of the KAS factor B genes in *Cuphea* are also 95-97% identical with each other. However there is only approximately 60% sequence identity between KAS factor B and KAS factor A clones either within the same or different species of *Cuphea*.

Example 2 Levels and Patterns of Expression

To examine tissue specificity of KAS expression in *Cuphea hookeriana*, Northern blot analysis was conducted using total RNA isolated from seed, root, leaf and flower tissue. Two separate but identical blots were hybridized with either chKAS B-31-7 or chKAS A-2-7 coding region probes. The data from this RNA blot analysis indicate that KAS B is expressed at a similar level in all tissues examined, whereas KAS A expression is detected only in the seed. These results also demonstrate a different level of expression for each of the synthases. KAS A is an abundant message, whereas KAS B is expressed at low levels. Furthermore, even under highly stringent hybridization conditions (65_C, 0.1 X SSC, 0.5% SDS), the KAS A probe hybridizes equally well with two seed transcripts of 2.3 and 1.9 kb. The larger hybridizing band is likely the transcript of the KAS A-2-7 gene since the size of its cDNA is 2046bp, and the number of clones obtained from cDNA screening corresponds well with the apparent mobility of the mRNA and its abundance on the blot.

Example 3 Expression of Plant KAS Genes in E.coli

DNA fragments encoding the mature polypeptide of the *Cuphea hookeriana* KAS A cDNAs and the *Cuphea pullcherrima* KAS B cDNAs were obtained by PCR and cloned into a QIAexpress expression vector (Qiagene). Experimental conditions for maximum level of expression were determined for all of these clones and the parameters for highest level of soluble fraction were identified. Cells are grown in ECLB media containing 1M sorbitol and 2.5 mM betaine overnight and subcultured as a 1:4 dilution in the same medium. Cells are then grown for 2 hours (to approximately .6-.8 O.D.) and induced with 0.4 mM IPTG and allowed to grow for 5 more hours.

Enzyme activity of the affinity purified recombinant enzymes obtained from over-expression of the chKAS A-2-7 and cpuKAS B/8-7A clones was measured using a wide range of acyl-ACP substrates (6:0- to 16:1-ACP). The activity profile for cpuKAS B/8-7A is provided in Fig.10. The data demonstrate that the enzyme is active with all acyl-ACP substrates examined, although activity on 6:0 to 14:0-ACP substrates is substantially greater than the activity on 16:0 and 16:1 substrates.

The activity profile of the *C. hookeriana* KAS A clones chKAS A-2-7 and chKAS A-1-6 is provided in Figure 11. The *C. hookeriana* KAS A clones are most active with C:6, and have the least activity with C:16:0 substrates. However, the activity of this clone on even the preferred C6:0 substrate

is 50 fold lower than the activity of the *C. pullcherrima* KAS B clones.

A fragment containing the mature protein encoding portion of a *R. communis* KAS factor A clone was also cloned into a QIAexpress expression vector, expressed in *E. coli* and the enzyme affinity purified as described above. The activity profile for castor KAS A is provided in Figure 12. Highest activity is observed with C14:0 substrates, although some activity is also seen with C6:0 and C16:1. In comparison, the activity profile obtained from purified *R. communis* KAS factor B also using the QIAexpress expression system is provided in Figure 13. The KAS B clone demonstrates substantially higher levels of activity (10 fold and higher) than the *R. communis* KAS A clone. The preference of the KAS factor B for 6:0- to 14:0-ACP substrates is consistent with the previous observations that this protein provides KAS I activity.

Example 4 KAS and TE Expression in Transgenic Seed

Both the CpFatB1 (*C. hookeriana* thioesterase cDNA; Dehesh *et al.* (1996) *Plant Physiol. 110*:203-210) and the chKAS A-2-7 were PCR amplified, sequenced, and cloned into a napin expression cassette. The napin/cp FatB1 and the napin/KAS A-2-7 fusions were ligated separately into the binary vector pCGN1558 (McBride and Summerfelt (*Pl.Mol.Biol.* (1990) *14*:269-276) and transformed into *A. tumefaciens*, EHA101. The resulting CpFatB1 binary construct is pCGN5400 and the chKAS A-2-7 construct is pCGN5401. *Agrobacterium* mediated transformation of a *Brassica napus* canola variety

was carried out as described by Radke *et al.* (*Theor. Appl. Genet.* (1988) 75:685-694; *Plant Cell Reports* (1992) *11*:499-505). Several transgenic events were produced for each of the pCGN5400 and pCGN5401 constructs.

A double gene construct containing a napin/cpFatB1 expression construct in combination with a napin/chKAS A-2-7 expression construct was also assembled, ligated into a binary vector and used for co-cultivation of a canola *Brassica* variety. The binary construct containing the chFatB1 and chKAS A-2-7 expression constructs is pCGN5413.

Fatty acid analysis of 26 transgenic lines containing chKAS A-2-7 (5401 lines) showed no significant changes in the oil content or profile as compared to similar analyses of wild type canola seeds of the transformed variety.

Fatty acid analysis of 36 transgenic lines containing cpFatB1 (5400 lines) showed increased levels of C:8 and C:10 in transgenic seeds. The highest level of C:8 observed in a pool seed sample was 4.2 mol%. The C:10 levels were between 30 and 35% of the C:8 content. Fatty acid analysis of 25 transgenic lines containing the TE/KAS A tandem (5413 lines) demonstrated an overall increase in both C:8 and C:10 levels relative to those observed with TE containing lines (5400) alone. In lines containing the cpFatB1 construct alone, the average level of C:8 average were 1.5 mol%, whereas the C:8 average levels in TE/KAS A tandem containing lines was 2.37 mol%. The ratio of C:8 to C:10 remained constant in both populations. The number of transgenic events relative to the C:8 content are presented in Figure 14. These data show that the transgenic events with tandem TE/KAS A construct

yield more lines with higher levels of C:8 than those events with single TE construct. For example, several lines containing nearly 7 mole% C8 were obtained with the TE/KAS A pCGN5413 construct, whereas the highest C8 containing line from the pCGN5400 TE alone transformation contained 4.2 mole% C8.

Half seed analysis of the T3 generation of transgenic canola plants expressing a ChFatB2 (*C. hookeriana* thioesterase; Dehesh *et al.* (1996) *The Plant Journal 9*:167-172) indicate that these plant can accumulate up to 22 weight% (33 mol%) of 8:0 and 10:0 fatty acids (4804-22-357). Segregation analysis shows that these transformants contain two loci and that they are now homozygous. Selected plants grown from these half seeds were transferred into the greenhouse and later crossed with T1 transformants that had been transformed with either *Cuphea hookeriana* KAS A (5401) alone or KAS A/CpFatB1 double constructs (5413).

Fatty acid analysis of several events resulting from the crosses between transgenic lines containing ChFatB2 (4804-22-357) and chKAS A-2-7 (5401-9), reveal an increase in the ratio of C:10/C:8 levels (Figure 15). This C:10/C:8 ratio in nearly all of the transgenic events containing ChFatB2 TE alone fluctuates between 3 and 6, whereas in the F1 generation of transgenic containing both the TE and the KAS A-2-7, the ratio can be as high as 22. This increase in C:10 levels is accompanied by an increase in the total C:8 and C:10 content (Figure 16). The sum of the C:8 and C:10 fatty acids in the heterozygous F1 lines is as high as those in the homozygous parent line (4804-22-357), whereas the

heterozygous lines usually contain substantially less C:8 and C:10 than the homozygous lines.

Similar results were observed in F1 generation seeds resulting from crosses performed between 4804-22-357 (ChFatB2) and the 5413-17 event (CpFatB1 and chKAS A-2-7 tandem). Levels of C:8 and C:10 in the 5413-17 line were 6.3 and 2.8 mol% respectively. Data presented in Figure 17 show that there is shift towards C:10 fatty acids as was observed with the 4804-22-357 (ChFatB2) x 5401-9 (chKAS A-2-7) crosses. Furthermore, Figure 18 indicates the presence of two separate populations of heterozygotes. Those containing approximately 9-11 weight percent C:10 + C:8 are believed to represent offspring containing a single copy of the ChFatB1 TE gene and no copies of the CpFatB1 and chKAS A genes from 5413. Those plants containing approximately 15-20 weight percent C:10 + C:8 are believed to represent the heterozygotes containing a single ChFatB1 TE gene as well as the CpFatB1 and chKAS A genes from 5413. Thus, the level of the C:10 + C:8 fatty acids does not decrease to 50% of that detected in parent lines when a copy of the ChKAS A gene is present.

To further characterize the chain length specificity of the *Cuphea hookeriana* KAS A enzyme, crosses between transgenic *Brassica napus* lines containing a California Bay (*Umbellularia californica*) 12:0 specific thioesterase, Uc FatB1 (USPN 5,344,771) and chKAS A-2-7 (5401-9) were made. Half seed analysis of transgenic plants containing Uc fatB1 have previuosly indicated that these plants can accumulate up to 52 mol% C12:0 in the seed oil of homozygous dihaploid

lines (LA86DH186). Crosses between the line LA86DH186 and untransformed control *Brassica* demonstrated a decrease in the C12:0 levels.

However, crosses between LA86DH186 and the 5401-9 hemizygous line led to an accumulation of up to 57 mol% C12:0 in the seed oil of F1 progeny (Figure 19). Interestingly, in crosses with LA86DH186 x untransformed control line and LA86DH186 x 5401-9, levels of C14:0 in the seeds of the F1 progeny decreased to 50% of the levels obtained in homozygous LA86DH186 lines (Figure 20). Furthermore, increases in the proportion of C12:0 fatty acid resulted in a substantial decline in the proportions of all the long-chain fatty acyl groups (C16:0, C18:0, C18:2, and C18:3). These results indicate that the ChKAS A-2-7 is an enzyme with substrate specificity ranging from C6:0 to C10:0-ACP, and that its over-expression ultimately reduces the longer chain acyl-ACP pools.

Further evidence is obtained in support of the chain length specificity of the ChKAS A-2-7 in crosses of the 5401-9 line with a transgenic line (5266) expressing an 18:1/18:0 TE from *Garcinia mangostana* (GarmFatA1, US patent application No. 08/440,845). Transgenic *Brassica* line 5266 has been shown to accumulate up to 24 mol% C18:0 in the seed oil of homozygous lines (Figure 21). However, in the seed oil of F1 progeny of crosses between 5266 and 5401-9 levels of C18:0 were reduced to approximately 12 mol%. Furthermore, levels of C16:0 generated from these crosses was similar to the levels obtained from the seed oil of nontransgenic control plants.

Example 5 ***In vitro*** **Analysis of Plant KAS Enzymes**

Seed extracts were prepared from developing seeds of nontransgenic controls or transgenic *Brassica* expressing chKAS A-2-7 as described in Slabaugh *et al.*(*Plant Journal*, 1998 in press) and Leonard *et al.* (Plant Journal, 1998, in press). *In vitro* fatty acid synthesis assays were performed as described by Post-Beittenmiller (*J. Biol. Chem.* (1991), 266:1858-1865). Extracts were concentrated by ammonium sulfate precipitation and desalting using P-6 columns (Bio-Rad, Hercules, CA). Reactions (65µl) contained 0.1M Tris/HCl (pH 8.0), 1 mM dithiothreitol, 25 mM recombinant spinach ACP1, 1 mM NADH, 2 mM NADPH, 50 µM malonyl-CoA, 10 µM [1-^{14}C]acetyl-CoA (50 mCi/mmol), 1mg/ml BSA, and 0.25 mg/ml seed protein. Selected seed extracts were preincubated with cerulenin at 23°C for 10 min. Reaction products were separated on an 18% acrlamide gel containing 2.25M urea, electroblotted onto to nitrocellulose and quntitated by phosporimaging using Image QuaNT software (Molecular Dynamics, Sunnyvale, CA). Authentic acyl-ACPs were run in parallel, immunoblotted and finally detected by anti-ACP serum to confirm fatty acid chain lengths.

The results (Figure 22) indicate that the fatty acid synthesis capabilities of transgenic *Brasica* (5401-9) seed extracts was greater than that obtained from in the nontransgenic controls as measured by the relative abundance of C8:0- and C10:0-ACP at all time points tested. In addition, pretreatment of the extracts with cerulenin, markedly reduced the synthesis of longer chain fatty acids in both the transgenic and nontransgenic control seed

extracts. However, the extension of the spinach-ACP was much less inhibited in the seed extracts from the transgenic lines than in the seed extracts of nontransgenic control *Brassica*.

These data further support that Ch KAS A-2-7 is a condensing enzyme active on medium chain acyl-ACPs, and that expression of this enzyme in plants results in enlarged substrate pools to be hydrolyzed by medium-chain specific thioesterases. Furthermore, these data suggest that chKAS A-2-7 also is a cerulenin-resistant condensing enzyme.

All publications and patent applications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claim.

MISSING UPON TIME OF PUBLICATION

13. The construct of Claim 5 wherein said encoding sequence is cpuKAS A/p8-9A.

14. The construct of Claim 5 wherein said encoding sequence is chKASIII-27.

15. An improved method for producing medium-chain fatty acids in transgenic plant seeds by expression of a plant medium-chain thioesterase protein heterologous to said transgenic plant,

the improvement comprising expression of a plant synthase factor protein heterologous to said transgenic plant in conjunction with expression of said plant medium-chain thioesterase, whereby the percentage of medium-chain fatty acids produced in seeds expressing both a plant synthase factor protein and a plant medium-chain thioesterase protein is increased as compared to the percentage of medium-chain fatty acids produced in seeds expressing only said plant medium-chain thioesterase protein.

16. The method of Claim 15 wherein said medium-chain thioesterase protein is a ChFatB2 protein.

17. The method of Claim 15 wherein said medium-chain thioesterase protein is a CpFatB1 protein.

18. The method of Claim 15 wherein said medium-chain thioesterase protein is a C12 preferring thioesterase from California bay.

19. The method of Claim 15 wherein said plant synthase factor protein is expressed from a construct according to Claim 1.

20. The method of Claim 19 wherein said synthase factor A protein is from a *Cuphea* species.

21. The method of Claim 20 wherein said *Cuphea* species is *C. hookeriana* or *C. pullcherrima*.

22. A method of altering the medium-chain fatty acid composition in plant seeds expressing a heterologous plant medium-chain preferring thioesterase, wherein said method comprises

providing for expression of a plant synthase factor protein heterologous to said transgenic plant in conjunction with expression of a plant medium-chain thioesterase protein heterologous to said transgenic plant, whereby the composition of medium-chain fatty acids produced in said seeds is modified as compared to the composition of medium-chain fatty acids produced in seeds expressing said plant medium-chain thioesterase protein in the absence of expression of said plant synthase factor protein.

23. The method of Claim 22 wherein said medium-chain thioesterase protein is a ChFatB2 protein.

24. The method of Claim 22 wherein said medium-chain thioesterase protein is a CpFatB1 protein.

25. The method of Claim 22 wherein said medium-chain thioesterase protein is a C12 preferring thioesterase from California bay.

26. The method of Claim 22 wherein said plant synthase factor protein is expressed from a construct according to Claim 1.

27. The method of Claim 26 wherein said synthase factor A protein is from a *Cuphea* species.

28. The method of Claim 27 wherein said *Cuphea* species is *C. hookeriana* or *C. pullcherrima*.

29. The method of Claim 22 wherein said fatty acid composition is enriched for C10 fatty acids.

30. The method of Claim 22 wherein said fatty acid composition is enriched for C12 fatty acids.

31. The method of Claim 22 wherein said fatty acid composition is enriched for at least one medium chain fatty acid and at least one other medium chain fatty acid is decreased.

32. The method of Claim 31 wherein said enriched fatty acid is C12 and said decreased fatty acid is C14.

(54) Title: METHODS AND COMPOSITIONS FOR SYNTHESIS OF LONG CHAIN POLYUNSATURATED FATTY ACIDS

(57) Abstract

The present invention relates to fatty acid desaturases able to catalyze the conversion of oleic acid to linoleic acid, linoleic acid to γ-linolenic acid, or of alpha-linolenic acid to stearidonic acid. Nucleic acid sequences encoding desaturases, nucleic acid sequences which hybridize thereto, DNA constructs comprising a desaturase gene, and recombinant host microorganism or animal expressing increased levels of a desaturase are described. Methods for desaturating a fatty acid and for producing a desaturated fatty acid by expressing increased levels of a desaturase are disclosed. Fatty acids, and oils containing them, which have been desaturated by a desaturase produced by recombinant host microorganisms or animals are provided. Pharmaceutical compositions, infant formulas or dietary supplements containing fatty acids which have been desaturated by a desaturase produced by a recombinant host microorganism or animal also are described.

METHODS AND COMPOSITIONS FOR SYNTHESIS OF LONG CHAIN POLYUNSATURATED FATTY ACIDS

RELATED APPLICATIONS

This application is a contiuation-in-part application of United States Patent Application Serial No. 08/834,655 filed April 11, 1997.

INTRODUCTION

Field of the Invention

This invention relates to modulating levels of enzymes and/or enzyme components relating to production of long chain poly-unsaturated fatty acids (PUFAs) in a microorganism or animal.

Background

Two main families of polyunsaturated fatty acids (PUFAs) are the ω3 fatty acids, exemplified by eicosapentaenoic acid (EPA), and the ω6 fatty acids, exemplified by arachidonic acid (ARA). PUFAs are important components of the plasma membrane of the cell, where they may be found in such forms as phospholipids. PUFAs are necessary for proper development, particularly in the developing infant brain, and for tissue formation and repair. PUFAs also serve as precursors to other molecules of importance in human beings and animals, including the prostacyclins, eicosanoids, leukotrienes and prostaglandins. Four major long chain PUFAs of importance include docosahexaenoic acid (DHA) and EPA, which are primarily found in different types of fish oil, γ-linolenic acid (GLA), which is found in the seeds of a number of plants, including evening primrose (*Oenothera biennis*), borage (*Borago officinalis*) and black currants (*Ribes nigrum*), and stearidonic acid (SDA), which is found in marine oils and plant seeds. Both GLA and another important long chain PUFA, arachidonic acid (ARA), are found in filamentous fungi. ARA can be purified from animal tissues including liver and adrenal gland. GLA, ARA, EPA and

SDA are themselves, or are dietary precursors to, important long chain fatty acids involved in prostaglandin synthesis, in treatment of heart disease, and in development of brain tissue.

For DHA, a number of sources exist for commercial production including a variety of marine organisms, oils obtained from cold water marine fish, and egg yolk fractions. For ARA, microorganisms including the genera *Mortierella, Entomophthora, Phytium* and *Porphyridium* can be used for commercial production. Commercial sources of SDA include the genera *Trichodesma and Echium*. Commercial sources of GLA include evening primrose, black currants and borage. However, there are several disadvantages associated with commercial production of PUFAs from natural sources. Natural sources of PUFAs, such as animals and plants, tend to have highly heterogeneous oil compositions. The oils obtained from these sources therefore can require extensive purification to separate out one or more desired PUFAs or to produce an oil which is enriched in one or more PUFA. Natural sources also are subject to uncontrollable fluctuations in availability. Fish stocks may undergo natural variation or may be depleted by overfishing. Fish oils have unpleasant tastes and odors, which may be impossible to economically separate from the desired product, and can render such products unacceptable as food supplements. Animal oils, and particularly fish oils, can accumulate environmental pollutants. Weather and disease can cause fluctuation in yields from both fish and plant sources. Cropland available for production of alternate oil-producing crops is subject to competition from the steady expansion of human populations and the associated increased need for food production on the remaining arable land. Crops which do produce PUFAs, such as borage, have not been adapted to commercial growth and may not perform well in monoculture. Growth of such crops is thus not economically competitive where more profitable and better established crops can be grown. Large scale fermentation of organisms such as *Mortierella* is also expensive. Natural animal tissues contain low amounts of ARA and are difficult to process. Microorganisms such as *Porphyridium* and *Mortierella* are difficult to cultivate on a commercial scale.

Dietary supplements and pharmaceutical formulations containing PUFAs can retain the disadvantages of the PUFA source. Supplements such as fish oil capsules can contain low levels of the particular desired component and thus require large dosages. High dosages result in ingestion of high levels of undesired components, including contaminants. Unpleasant tastes and odors of the supplements can make such regimens undesirable, and may inhibit compliance by the patient. Care must be taken in providing fatty acid supplements, as overaddition may result in suppression of endogenous biosynthetic pathways and lead to competition with other necessary fatty acids in various lipid fractions *in vivo*, leading to undesirable results. For example, Eskimos having a diet high in ω3 fatty acids have an increased tendency to bleed (U.S. Pat. No. 4,874,603).

A number of enzymes are involved in PUFA biosynthesis. Linoleic acid (LA, 18:2 Δ9, 12) is produced from oleic acid (18:1 Δ9) by a Δ12-desaturase. GLA (18:3 Δ6, 9, 12) is produced from linoleic acid (LA, 18:2 Δ9, 12) by a Δ6-desaturase. ARA (20:4 Δ5, 8, 11, 14) production from dihomo-γ-linolenic acid (DGLA, 20:3 Δ8, 11, 14) is catalyzed by a Δ5-desaturase. However, animals cannot desaturate beyond the Δ9 position and therefore cannot convert oleic acid (18:1 Δ9) into linoleic acid (18:2 Δ9, 12). Likewise, α-linolenic acid (ALA, 18:3 Δ9, 12, 15) cannot be synthesized by mammals. Other eukaryotes, including fungi and plants, have enzymes which desaturate at positions Δ12 and Δ15. The major poly-unsaturated fatty acids of animals therefore are either derived from diet and/or from desaturation and elongation of linoleic acid (18:2 Δ9, 12) or α-linolenic acid (18:3 Δ9, 12, 15). Therefore it is of interest to obtain genetic material involved in PUFA biosynthesis from species that naturally produce these fatty acids and to express the isolated material in a microbial or animal system which can be manipulated to provide production of commercial quantities of one or more PUFAs. Thus there is a need for fatty acid desaturases, genes encoding them, and recombinant methods of producing them. A need further exists for oils containing higher relative proportions of and/or

enriched in specific PUFAs. A need also exists for reliable economical methods of producing specific PUFAs.

Relevant Literature

Production of γ-linolenic acid by a Δ6-desaturase is described in USPN 5,552,306. Production of 8, 11-eicosadienoic acid using *Mortierella alpina* is disclosed in USPN 5,376,541. Production of docosahexaenoic acid by dinoflagellates is described in USPN 5,407,957. Cloning of a Δ6-palmitoyl-acyl carrier protein desaturase is described in PCT publication WO 96/13591 and USPN 5,614,400. Cloning of a Δ6-desaturase from borage is described in PCT publication WO 96/21022. Cloning of Δ9-desaturases is described in the published patent applications PCT WO 91/13972, EP 0 550 162 A1, EP 0 561 569 A2, EP 0 644 263 A2, and EP 0 736 598 A1, and in USPN 5,057,419. Cloning of Δ12-desaturases from various organisms is described in PCT publication WO 94/11516 and USPN 5,443,974. Cloning of Δ15-desaturases from various organisms is described in PCT publication WO 93/11245. All publications and U.S. patents or applications referred to herein are hereby incorporated in their entirety by reference.

SUMMARY OF THE INVENTION

Novel compositions and methods are provided for preparation of poly-unsaturated long chain fatty acids. The compositions include nucleic acid encoding a Δ6- and Δ12- desaturase and/or polypeptides having Δ6- and/or Δ12-desaturase activity, the polypeptides, and probes isolating and detecting the same. The methods involve growing a host microorganism or animal expressing an introduced gene or genes encoding at least one desaturase, particularly a Δ6-, Δ9-, Δ12- or Δ15-desaturase. The methods also involve the use of antisense constructs or gene disruptions to decrease or eliminate the expression level of undesired desaturases. Regulation of expression of the desaturase polypeptide(s) provides for a relative increase in desired desaturated PUFAs as a result of altered concentrations of enzymes and substrates involved

in PUFA biosynthesis. The invention finds use, for example, in the large scale production of GLA, DGLA, ARA, EPA, DHA and SDA.

In a preferred embodiment of the invention, an isolated nucleic acid comprising: a nucleotide sequence depicted in Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3), a polypeptide encoded by a nucleotide sequence according Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3), and a purified or isolated polypeptide comprising an amino acid sequence depicted in Figure 3A-E (SEQ ID NO: 2) or Figure 5A-D (SEQ ID NO: 4). In another embodiment of the invention, provided is an isolated nucleic acid encoding a polypeptide having an amino acid sequence depicted in Figure 3A-E (SEQ ID NO: 2) or Figure 5A-D (SEQ ID NO: 4).

Also provided is an isolated nucleic acid comprising a nucleotide sequence which encodes a polypeptide which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end, wherein said nucleotide sequence has an average A/T content of less than about 60%. In a preferred embodiment, the isolated nucleic acid is derived from a fungus, such as a fungus of the genus *Mortierella*. More preferred is a fungus of the species *Mortierella alpina*.

In another preferred embodiment of the invention, an isolated nucleic acid is provided wherein the nucleotide sequence of the nucleic acid is depicted in Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3). The invention also provides an isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end, wherein the polypeptide is a eukaryotic polypeptide or is derived from a eukaryotic polypeptide, where a preferred eukaryotic polypeptide is derived from a fungus.

The present invention further includes a nucleic acid sequence which hybridizes to Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3). Preferred is an isolated nucleic acid having a nucleotide sequence with at least about 50% homology to Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3). The invention also includes an isolated nucleic acid having a nucleotide sequence with at least about 50% homology to Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3). In a preferred embodiment, the

nucleic acid of the invention includes a nucleotide sequence which encodes an amino acid sequence depicted in Figure 3A-D (SEQ ID NO: 2) which is selected from the group consisting of amino acid residues 50-53, 39-43, 172-176, 204-213, and 390-402.

Also provided by the present invention is a nucleic acid construct comprising a nucleotide sequence depicted in a Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3) linked to a heterologous nucleic acid. In another embodiment, a nucleic acid construct is provided which comprises a nucleotide sequence depicted in a Figure 3A-E (SEQ ID NO: 1) or Figure 5A-D (SEQ ID NO: 3) operably associated with an expression control sequence functional in a host cell. The host cell is either eukaryotic or prokaryotic. Preferred eukaryotic host cells are those selected from the group consisting of a mammalian cell, an insect cell, a fungal cell, and an algae cell. Preferred mammalian cells include an avian cell, a preferred fungal cell includes a yeast cell, and a preferred algae cell is a marine algae cell. Preferred prokaryotic cells include those selected from the group consisting of a bacteria, a cyanobacteria, cells which contain a bacteriophage, and/or a virus. The DNA sequence of the recombinant host cell preferably contains a promoter which is functional in the host cell, which promoter is preferably inducible. In a more preferred embodiment, the microbial cell is a fungal cell of the genus *Mortierella*, with a more preferred fungus is of the species *Mortierella alpina*.

In addition, the present invention provides a nucleic acid construct comprising a nucleotide sequence which encodes a polypeptide comprising an amino acid sequence which corresponds to or is complementary to an amino acid sequence depicted in Figure 3A-E (SEQ ID NO: 2) or Figure 5A-D (SEQ ID NO: 4), wherein the nucleic acid is operably associated with an expression control sequence functional in a microbial cell, wherein the nucleotide sequence encodes a functionally active polypeptide which desaturates a fatty acid molecule at carbon 6 or carbon 12 from the carboxyl end of a fatty acid molecule. Another embodiment of the present invention is a nucleic acid construct comprising a nucleotide sequence which encodes a functionally active Δ6-desaturase having an amino acid sequence which corresponds to or is

complementary to all of or a portion of an amino acid sequence depicted in a Figure 3A-E (SEQ ID NO: 2), wherein the nucleotide sequence is operably associated with a transcription control sequence functional in a host cell.

Yet another embodiment of the present invention is a nucleic acid construct comprising a nucleotide sequence which encodes a functionally active Δ12-desaturase having an amino acid sequence which corresponds to or is complementary to all of or a portion of an amino acid sequence depicted in a Figure 5A-D (SEQ ID NO: 4), wherein the nucleotide sequence is operably associated with a transcription control sequence functional in a host cell. The host cell, is either a eukaryotic or prokaryotic host cell. Preferred eukaryotic host cells are those selected from the group consisting of a mammalian cell, an insect cell, a fungal cell, and an algae cell. Preferred mammalian cells include an avian cell, a preferred fungal cell includes a yeast cell, and a preferred algae cell is a marine algae cell. Preferred prokaryotic cells include those selected from the group consisting of a bacteria, a cyanobacteria, cells which contain a bacteriophage, and/or a virus. The DNA sequence of the recombinant host cell preferably contains a promoter which is functional in the host cell and which preferably is inducible. A preferred recombinant host cell is a microbial cell such as a yeast cell, such as a *Saccharomyces* cell.

The present invention also provides a recombinant microbial cell comprising at least one copy of a nucleic acid which encodes a functionally active *Mortierella alpina* fatty acid desaturase having an amino acid sequence as depicted in Figure 3A-E (SEQ ID NO: 2), wherein the cell or a parent of the cell was transformed with a vector comprising said DNA sequence, and wherein the DNA sequence is operably associated with an expression control sequence. In a preferred embodiment, the cell is a microbial cell which is enriched in 18:2 fatty acids, particularly where the microbial cell is from a genus selected from the group consisting of a prokaryotic cell and eukaryotic cell. In another preferred embodiment, the microbial cell according to the invention includes an expression control sequence which is endogenous to the microbial cell.

Also provided by the present invention is a method for production of GLA in a host cell, where the method comprises growing a host culture having a plurality of host cells which contain one or more nucleic acids encoding a polypeptide which converts LA to GLA, wherein said one or more nucleic acids is operably associated with an expression control sequence, under conditions whereby said one or more nucleic acids are expressed, whereby GLA is produced in the host cell. In several preferred embodiments of the methods, the polypeptide employed in the method is a functionally active enzyme which desaturates a fatty acid molecule at carbon 6 from the carboxyl end of a fatty acid molecule; the said one or more nucleic acids is derived from a *Mortierella alpina*; the substrate for the polypeptide is exogenously supplied; the host cells are microbial cells; the microbial cells are yeast cells, such as *Saccharomyces* cells; and the growing conditions are inducible.

Also provided is an oil comprising one or more PUFA, wherein the amount of said one or more PUFAs is approximately 0.3-30% arachidonic acid (ARA), approximately 0.2-30% dihomo-γ-linolenic acid (DGLA), and approximately 0.2-30% γ-linoleic acid (GLA). A preferred oil of the invention is one in which the ratio of ARA:DGLA:GLA is approximately 1.0:19.0:30 to 6.0:1.0:0.2. Another preferred embodiment of the invention is a pharmaceutical composition comprising the oils in a pharmaceutically acceptable carrier. Further provided is a nutritional composition comprising the oils of the invention. The nutritional compositions of the invention preferably are administered to a mammalian host parenterally or internally. A preferred composition of the invention for internal consumption is an infant formula. In a preferred embodiment, the nutritional compositions of the invention are in a liquid form or a solid form, and can be formulated in or as a dietary supplement, and the oils provided in encapsulated form. The oils of the invention can be free of particular components of other oils and can be derived from a microbial cell, such as a yeast cell.

The present invention further provides a method for desaturating a fatty acid. In a preferred embodiment the method comprises culturing a recombinant microbial cell according to the invention under conditions suitable for

expression of a polypeptide encoded by said nucleic acid, wherein the host cell further comprises a fatty acid substrate of said polypeptide. Also provided is a fatty acid desaturated by such a method, and an oil composition comprising a fatty acid produced according to the methods of the invention.

The present invention further includes a purified nucleotide sequence or polypeptide sequence that is substantially related or homologous to the nucleotide and peptide sequences presented in SEQ ID NO:1 - SEQ ID NO:40. The present invention is further directed to methods of using the sequences presented in SEQ ID NO:1 to SEQ ID NO:40 as probes to identify related sequences, as components of expression systems and as components of systems useful for producing transgenic oil.

The present invention is further directed to formulas, dietary supplements or dietary supplements in the form of a liquid or a solid containing the long chain fatty acids of the invention. These formulas and supplements may be administered to a human or an animal.

The formulas and supplements of the invention may further comprise at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

The formulas of the present invention may further include at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

The present invention is further directed to a method of treating a patient having a condition caused by insuffient intake or production of polyunsaturated fatty acids comprising administering to the patient a dietary substitute of the invention in an amount sufficient to effect treatment of the patient.

The present invention is further directed to cosmetic and pharmaceutical compositions of the material of the invention.

The present invention is further directed to transgenic oils in pharmaceutically acceptable carriers. The present invention is further directed to nutritional supplements, cosmetic agents and infant formulae containing transgenic oils.

The present invention is further directed to a method for obtaining altered long chain polyunsaturated fatty acid biosynthesis comprising the steps of: growing a microbe having cells which contain a transgene which encodes a transgene expression product which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end of said fatty acid molecule, wherein the trangene is operably associated with an expression control sequence, under conditions whereby the transgene is expressed, whereby long chain polyunsaturated fatty acid biosynthesis in the cells is altered.

The present invention is further directed toward pharmaceutical compositions comprising at least one nutrient selected from the group consisting of a vitamin, a mineral, a carbohydrate, a sugar, an amino acid, a free fatty acid, a phospholipid, an antioxidant, and a phenolic compound.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows possible pathways for the synthesis of arachidonic acid (20:4 Δ5, 8, 11, 14) and stearidonic acid (18:4 Δ6, 9, 12, 15) from palmitic acid (C_{16}) from a variety of organisms, including algae, *Mortierella* and humans. These PUFAs can serve as precursors to other molecules important for humans and other animals, including prostacyclins, leukotrienes, and prostaglandins, some of which are shown.

Figure 2 shows possible pathways for production of PUFAs in addition to ARA, including EPA and DHA, again compiled from a variety of organisms.

Figure 3A-E shows the DNA sequence of the *Mortierella alpina* Δ6-desaturase and the deduced amino acid sequence:

Figure 3A-E (SEQ ID NO 1 Δ6 DESATURASE cDNA)

Figure 3A-E (SEQ ID NO 2 Δ6 DESATURASE AMINO ACID)

Figure 4 shows an alignment of a portion of the *Mortierella alpina* Δ6-desaturase amino acid sequence with other related sequences.

Figure 5A-D shows the DNA sequence of the *Mortierella alpina* Δ12-desaturase and the deduced amino acid sequence:

Figure 5A-D (SEQ ID NO 3 Δ12 DESATURASE cDNA)

Figure 5A-D (SEQ ID NO 4 Δ12 DESATURASE AMINO ACID).

Figures 6A and 6B show the effect of different expression constructs on expression of GLA in yeast.

Figures 7A and 7B show the effect of host strain on GLA production.

Figures 8A and 8B show the effect of temperature on GLA production in *S. cerevisiae* strain SC334.

Figure 9 shows alignments of the protein sequence of the Ma 29 and contig 253538a.

Figure 10 shows alignments of the protein sequence of Ma 524 and contig 253538a.

BRIEF DESCRIPTION OF THE SEQUENCE LISTINGS

SEQ ID NO:1 shows the DNA sequence of the *Mortierella alpina* Δ6-desaturase.

SEQ ID NO:2 shows the protein sequence of the *Mortierella alpina* Δ6-desaturase.

SEQ ID NO:3 shows the DNA sequence of the *Mortierella alpina* Δ12-desaturase.

SEQ ID NO:4 shows the protein sequence of the *Mortierella alpina* Δ12-desaturase.

SEQ ID NO:5-11 show various desaturase sequences.

SEQ ID NO:13-18 show various PCR primer sequences.

SEQ ID NO:19 and SEQ ID NO:20 show the nucleotide and amino acid sequence of a *Dictyostelium discoideum* desaturase.

SEQ ID NO:21 and SEQ ID NO:22 show the nucleotide and amino acid sequence of a *Phaeodactylum tricornutum* desaturase.

SEQ ID NO:23-26 show the nucleotide and deduced amino acid sequence of a *Schizochytrium* cDNA clone.

SEQ ID NO: 27-33 show nucleotide sequences for human desaturases.

SEQ ID NO:34 - SEQ ID NO:40 show peptide sequences for human desaturases.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to ensure a complete understanding of the invention, the following definitions are provided:

Δ5-Desaturase: Δ5 desaturase is an enzyme which introduces a double bond between carbons 5 and 6 from the carboxyl end of a fatty acid molecule.

Δ6-Desaturase: Δ6-desaturase is an enzyme which introduces a double bond between carbons 6 and 7 from the carboxyl end of a fatty acid molecule.

Δ9-Desaturase: Δ9-desaturase is an enzyme which introduces a double bond between carbons 9 and 10 from the carboxyl end of a fatty acid molecule.

Δ12-Desaturase: Δ12-desaturase is an enzyme which introduces a double bond between carbons 12 and 13 from the carboxyl end of a fatty acid molecule.

Fatty Acids: Fatty acids are a class of compounds containing a long hydrocarbon chain and a terminal carboxylate group. Fatty acids include the following:

Fatty Acid		
12:0	lauric acid	
16:0	palmitic acid	

Fatty Acid		
16:1	palmitoleic acid	
18:0	stearic acid	
18:1	oleic acid	Δ9-18:1
18:2 Δ5,9	taxoleic acid	Δ5,9-18:2
18:2 Δ6,9	6,9-octadecadienoic acid	Δ6,9-18:2
18:2	Linolenic acid	Δ9,12-18:2 (LA)
18:3 Δ6,9,12	Gamma-linolenic acid	Δ6,9,12-18:3 (GLA)
18:3 Δ5,9,12	Pinolenic acid	Δ5,9,12-18:3
18:3	alpha-linoleic acid	Δ9,12,15-18:3 (ALA)
18:4	stearidonic acid	Δ6,9,12,15-18:4 (SDA)
20:0	Arachidic acid	
20:1	Eicoscenic Acid	
22:0	behehic acid	
22:1	erucic acid	
22:2	docasadienoic acid	
20:4 ω6	arachidonic acid	Δ5,8,11,14-20:4 (ARA)
20:3 ω6	ω6-eicosatrienoic dihomo-gamma linolenic	Δ8,11,14-20:3 (DGLA)
20:5 ω3	Eicosapentanoic (Timnodonic acid)	Δ5,8,11,14,17-20:5 (EPA)
20:3 ω3	ω3-eicosatrienoic	Δ11,16,17-20:3
20:4 ω3	ω3-eicosatetraenoic	Δ8,11,14,17-20:4
22:5 ω3	Docosapentaenoic	Δ7,10,13,16,19-22:5 (ω3DPA)
22:6 ω3	Docosahexaenoic (cervonic acid)	Δ4,7,10,13,16,19-22:6 (DHA)
24:0	Lignoceric acid	

Taking into account these definitions, the present invention is directed to novel DNA sequences, DNA constructs, methods and compositions are provided which permit modification of the poly-unsaturated long chain fatty acid content of, for example, microbial cells or animals. Host cells are manipulated to express a sense or antisense transcript of a DNA encoding a polypeptide(s) which catalyzes the desaturation of a fatty acid. The substrate(s) for the expressed enzyme may be produced by the host cell or may be exogenously supplied. To achieve expression, the transformed DNA is

operably associated with transcriptional and translational initiation and termination regulatory regions that are functional in the host cell. Constructs comprising the gene to be expressed can provide for integration into the genome of the host cell or can autonomously replicate in the host cell. For production of linoleic acid (LA), the expression cassettes generally used include a cassette which provides for Δ12-desaturase activity, particularly in a host cell which produces or can take up oleic acid (U.S. Patent No. 5,443,974). Production of LA also can be increased by providing an expression cassette for a Δ9-desaturase where that enzymatic activity is limiting. For production of ALA, the expression cassettes generally used include a cassette which provides for Δ15- or ω3-desaturase activity, particularly in a host cell which produces or can take up LA. For production of GLA or SDA, the expression cassettes generally used include a cassette which provides for Δ6-desaturase activity, particularly in a host cell which produces or can take up LA or ALA, respectively. Production of ω6-type unsaturated fatty acids, such as LA or GLA, is favored in a host microorganism or animal which is incapable of producing ALA. The host ALA production can be removed, reduced and/or inhibited by inhibiting the activity of a Δ15- or ω3- type desaturase (see Figure 2). This can be accomplished by standard selection, providing an expression cassette for an antisense Δ15 or ω3 transcript, by disrupting a target Δ15- or ω3-desaturase gene through insertion, deletion, substitution of part or all of the target gene, or by adding an inhibitor of Δ15- or ω3-desaturase. Similarly, production of LA or ALA is favored in a microorganism or animal having Δ6-desaturase activity by providing an expression cassette for an antisense Δ6 transcript, by disrupting a Δ6-desaturase gene, or by use of a Δ6-desaturase inhibitor.

MICROBIAL PRODUCTION OF FATTY ACIDS

Microbial production of fatty acids has several advantages over purification from natural sources such as fish or plants. Many microbes are known with greatly simplified oil compositions compared with those of higher organisms, making purification of desired components easier. Microbial production is not subject to fluctuations caused by external variables such as

weather and food supply. Microbially produced oil is substantially free of contamination by environmental pollutants. Additionally, microbes can provide PUFAs in particular forms which may have specific uses. For example, *Spirulina* can provide PUFAs predominantly at the first and third positions of triglycerides; digestion by pancreatic lipases preferentially releases fatty acids from these positions. Following human or animal ingestion of triglycerides derived from *Spirulina*, these PUFAs are released by pancreatic lipases as free fatty acids and thus are directly available, for example, for infant brain development. Additionally, microbial oil production can be manipulated by controlling culture conditions, notably by providing particular substrates for microbially expressed enzymes, or by addition of compounds which suppress undesired biochemical pathways. In addition to these advantages, production of fatty acids from recombinant microbes provides the ability to alter the naturally occurring microbial fatty acid profile by providing new synthetic pathways in the host or by suppressing undesired pathways, thereby increasing levels of desired PUFAs, or conjugated forms thereof, and decreasing levels of undesired PUFAs.

PRODUCTION OF FATTY ACIDS IN ANIMALS

Production of fatty acids in animals also presents several advantages. Expression of desaturase genes in animals can produce greatly increased levels of desired PUFAs in animal tissues, making recovery from those tissues more economical. For example, where the desired PUFAs are expressed in the breast milk of animals, methods of isolating PUFAs from animal milk are well established. In addition to providing a source for purification of desired PUFAs, animal breast milk can be manipulated through expression of desaturase genes, either alone or in combination with other human genes, to provide animal milks substantially similar to human breast milk during the different stages of infant development. Humanized animal milks could serve as infant formulas where human nursing is impossible or undesired, or in cases of malnourishment or disease.

Depending upon the host cell, the availability of substrate, and the desired end product(s), several polypeptides, particularly desaturases, are of

interest. By "desaturase" is intended a polypeptide which can desaturate one or more fatty acids to produce a mono- or poly-unsaturated fatty acid or precursor thereof of interest. Of particular interest are polypeptides which can catalyze the conversion of stearic acid to oleic acid, of oleic acid to LA, of LA to ALA, of LA to GLA, or of ALA to SDA, which includes enzymes which desaturate at the Δ9, Δ12, (ω6), Δ15, (ω3) or Δ6 positions. By "polypeptide" is meant any chain of amino acids, regardless of length or post-translational modification, for example, glycosylation or phosphorylation. Considerations for choosing a specific polypeptide having desaturase activity include the pH optimum of the polypeptide, whether the polypeptide is a rate limiting enzyme or a component thereof, whether the desaturase used is essential for synthesis of a desired poly-unsaturated fatty acid, and/or co-factors required by the polypeptide. The expressed polypeptide preferably has parameters compatible with the biochemical environment of its location in the host cell. For example, the polypeptide may have to compete for substrate with other enzymes in the host cell. Analyses of the K_m and specific activity of the polypeptide in question therefore are considered in determining the suitability of a given polypeptide for modifying PUFA production in a given host cell. The polypeptide used in a particular situation is one which can function under the conditions present in the intended host cell but otherwise can be any polypeptide having desaturase activity which has the desired characteristic of being capable of modifying the relative production of a desired PUFA.

For production of linoleic acid from oleic acid, the DNA sequence used encodes a polypeptide having Δ12-desaturase activity. For production of GLA from linoleic acid, the DNA sequence used encodes a polypeptide having Δ6-desaturase activity. In particular instances, expression of Δ6-desaturase activity can be coupled with expression of Δ12-desaturase activity and the host cell can optionally be depleted of any Δ15-desaturase activity present, for example by providing a transcription cassette for production of antisense sequences to the Δ15-desaturase transcription product, by disrupting the Δ15-desaturase gene, or by using a host cell which naturally has, or has been mutated to have, low Δ15-desaturase activity. Inhibition of undesired desaturase pathways also can be

accomplished through the use of specific desaturase inhibitors such as those described in U.S. Patent No. 4,778,630. Also, a host cell for Δ6-desaturase expression may have, or have been mutated to have, high Δ12-desaturase activity. The choice of combination of cassettes used depends in part on the PUFA profile and/or desaturase profile of the host cell. Where the host cell expresses Δ12-desaturase activity and lacks or is depleted in Δ15-desaturase activity, overexpression of Δ6-desaturase alone generally is sufficient to provide for enhanced GLA production. Where the host cell expresses Δ9-desaturase activity, expression of a Δ12- and a Δ6-desaturase can provide for enhanced GLA production. When Δ9-desaturase activity is absent or limiting, an expression cassette for Δ9-desaturase can be used. A scheme for the synthesis of arachidonic acid (20:4 $\Delta^{5,8,11,14}$) from stearic acid (18:0) is shown in Figure 2. A key enzyme in this pathway is a Δ6-desaturase which converts the linoleic acid into γ-linolenic acid. Conversion of α-linolenic acid (ALA) to stearidonic acid by a Δ6-desaturase also is shown.

SOURCES OF POLYPEPTIDES HAVING DESATURASE ACTIVITY

A source of polypeptides having desaturase activity and oligonucleotides encoding such polypeptides are organisms which produce a desired polyunsaturated fatty acid. As an example, microorganisms having an ability to produce GLA or ARA can be used as a source of Δ6- or Δ12- desaturase activity. Such microorganisms include, for example, those belonging to the genera *Mortierella, Conidiobolus, Pythium, Phytophathora, Penicillium, Porphyridium, Coidosporium, Mucor, Fusarium, Aspergillus, Rhodotorula,* and *Entomophthora*. Within the genus *Porphyridium*, of particular interest is *Porphyridium cruentum.* Within the genus *Mortierella*, of particular interest are *Mortierella elongata, Mortierella exigua, Mortierella hygrophila, Mortierella ramanniana*, var. angulispora, and *Mortierella alpina*. Within the genus *Mucor*, of particular interest are *Mucor circinelloides* and *Mucor javanicus*.

DNAs encoding desired desaturases can be identified in a variety of ways. As an example, a source of the desired desaturase, for example genomic

or cDNA libraries from *Mortierella*, is screened with detectable enzymatically- or chemically-synthesized probes, which can be made from DNA, RNA, or non-naturally occurring nucleotides, or mixtures thereof. Probes may be enzymatically synthesized from DNAs of known desaturases for normal or reduced-stringency hybridization methods. Oligonucleotide probes also can be used to screen sources and can be based on sequences of known desaturases, including sequences conserved among known desaturases, or on peptide sequences obtained from the desired purified protein. Oligonucleotide probes based on amino acid sequences can be degenerate to encompass the degeneracy of the genetic code, or can be biased in favor of the preferred codons of the source organism. Oligonucleotides also can be used as primers for PCR from reverse transcribed mRNA from a known or suspected source; the PCR product can be the full length cDNA or can be used to generate a probe to obtain the desired full length cDNA. Alternatively, a desired protein can be entirely sequenced and total synthesis of a DNA encoding that polypeptide performed.

Once the desired genomic or cDNA has been isolated, it can be sequenced by known methods. It is recognized in the art that such methods are subject to errors, such that multiple sequencing of the same region is routine and is still expected to lead to measurable rates of mistakes in the resulting deduced sequence, particularly in regions having repeated domains, extensive secondary structure, or unusual base compositions, such as regions with high GC base content. When discrepancies arise, resequencing can be done and can employ special methods. Special methods can include altering sequencing conditions by using: different temperatures; different enzymes; proteins which alter the ability of oligonucleotides to form higher order structures; altered nucleotides such as ITP or methylated dGTP; different gel compositions, for example adding formamide; different primers or primers located at different distances from the problem region; or different templates such as single stranded DNAs. Sequencing of mRNA also can be employed.

For the most part, some or all of the coding sequence for the polypeptide having desaturase activity is from a natural source. In some situations, however, it is desirable to modify all or a portion of the codons, for example, to

enhance expression, by employing host preferred codons. Host preferred codons can be determined from the codons of highest frequency in the proteins expressed in the largest amount in a particular host species of interest. Thus, the coding sequence for a polypeptide having desaturase activity can be synthesized in whole or in part. All or portions of the DNA also can be synthesized to remove any destabilizing sequences or regions of secondary structure which would be present in the transcribed mRNA. All or portions of the DNA also can be synthesized to alter the base composition to one more preferable in the desired host cell. Methods for synthesizing sequences and bringing sequences together are well established in the literature. *In vitro* mutagenesis and selection, site-directed mutagenesis, or other means can be employed to obtain mutations of naturally occurring desaturase genes to produce a polypeptide having desaturase activity *in vivo* with more desirable physical and kinetic parameters for function in the host cell, such as a longer half-life or a higher rate of production of a desired polyunsaturated fatty acid.

Mortieralla alpina **Desaturase**

Of particular interest is the *Mortierella alpina* Δ6-desaturase, which has 457 amino acids and a predicted molecular weight of 51.8 kD; the amino acid sequence is shown in Figure 3. The gene encoding the *Mortierella alpina* Δ6-desaturase can be expressed in transgenic microorganisms or animals to effect greater synthesis of GLA from linoleic acid or of stearidonic acid from ALA. Other DNAs which are substantially identical to the *Mortierella alpina* Δ6-desaturase DNA, or which encode polypeptides which are substantially identical to the *Mortierella alpina* Δ6-desaturase polypeptide, also can be used. By substantially identical is intended an amino acid sequence or nucleic acid sequence exhibiting in order of increasing preference at least 60%, 80%, 90% or 95% homology to the *Mortierella alpina* Δ6-desaturase amino acid sequence or nucleic acid sequence encoding the amino acid sequence. For polypeptides, the length of comparison sequences generally is at least 16 amino acids, preferably at least 20 amino acids, or most preferably 35 amino acids. For nucleic acids, the length of comparison sequences generally is at least 50 nucleotides,

preferably at least 60 nucleotides, and more preferably at least 75 nucleotides, and most preferably, 110 nucleotides. Homology typically is measured using sequence analysis software, for example, the Sequence Analysis software package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wisconsin 53705, MEGAlign (DNAStar, Inc., 1228 S. Park St., Madison, Wisconsin 53715), and MacVector (Oxford Molecular Group, 2105 S. Bascom Avenue, Suite 200, Campbell, California 95008). Such software matches similar sequences by assigning degrees of homology to various substitutions, deletions, and other modifications. Conservative substitutions typically include substitutions within the following groups: glycine and alanine; valine, isoleucine and leucine; aspartic acid, glutamic acid, asparagine, and glutamine; serine and threonine; lysine and arginine; and phenylalanine and tyrosine. Substitutions may also be made on the basis of conserved hydrophobicity or hydrophilicity (Kyte and Doolittle, *J. Mol. Biol.* 157: 105-132, 1982), or on the basis of the ability to assume similar polypeptide secondary structure (Chou and Fasman, *Adv. Enzymol.* 47: 45-148, 1978).

Also of interest is the *Mortierella alpina* Δ12-desaturase, the nucleotide and amino acid sequence of which is shown in Figure 5. The gene encoding the *Mortierella alpina* Δ12-desaturase can be expressed in transgenic microorganisms or animals to effect greater synthesis of LA from oleic acid. Other DNAs which are substantially identical to the *Mortierella alpina* Δ12-desaturase DNA, or which encode polypeptides which are substantially identical to the *Mortierella alpina* Δ12-desaturase polypeptide, also can be used.

Other Desaturases

Encompassed by the present invention are related desaturases from the same or other organisms. Such related desaturases include variants of the disclosed Δ6- or Δ12-desaturase naturally occurring within the same or different species of *Mortierella*, as well as homologues of the disclosed Δ6- or Δ12-desaturase from other species. Also included are desaturases which, although

not substantially identical to the *Mortierella alpina* Δ6- or Δ12-desaturase, desaturate a fatty acid molecule at carbon 6 or 12, respectively, from the carboxyl end of a fatty acid molecule, or at carbon 12 or 6 from the terminal methyl carbon in an 18 carbon fatty acid molecule. Related desaturases can be identified by their ability to function substantially the same as the disclosed desaturases; that is, are still able to effectively convert LA to GLA, ALA to SDA or oleic acid to LA. Related desaturases also can be identified by screening sequence databases for sequences homologous to the disclosed desaturases, by hybridization of a probe based on the disclosed desaturases to a library constructed from the source organism, or by RT-PCR using mRNA from the source organism and primers based on the disclosed desaturases. Such desaturases include those from humans, *Dictyostelium discoideum* and *Phaeodactylum tricornum.*

The regions of a desaturase polypeptide important for desaturase activity can be determined through routine mutagenesis, expression of the resulting mutant polypeptides and determination of their activities. Mutants may include deletions, insertions and point mutations, or combinations thereof. A typical functional analysis begins with deletion mutagenesis to determine the N- and C-terminal limits of the protein necessary for function, and then internal deletions, insertions or point mutants are made to further determine regions necessary for function. Other techniques such as cassette mutagenesis or total synthesis also can be used. Deletion mutagenesis is accomplished, for example, by using exonucleases to sequentially remove the 5' or 3' coding regions. Kits are available for such techniques. After deletion, the coding region is completed by ligating oligonucleotides containing start or stop codons to the deleted coding region after 5' or 3' deletion, respectively. Alternatively, oligonucleotides encoding start or stop codons are inserted into the coding region by a variety of methods including site-directed mutagenesis, mutagenic PCR or by ligation onto DNA digested at existing restriction sites. Internal deletions can similarly be made through a variety of methods including the use of existing restriction sites in the DNA, by use of mutagenic primers via site directed mutagenesis or mutagenic PCR. Insertions are made through methods such as linker-scanning

mutagenesis, site-directed mutagenesis or mutagenic PCR. Point mutations are made through techniques such as site-directed mutagenesis or mutagenic PCR.

Chemical mutagenesis also can be used for identifying regions of a desaturase polypeptide important for activity. A mutated construct is expressed, and the ability of the resulting altered protein to function as a desaturase is assayed. Such structure-function analysis can determine which regions may be deleted, which regions tolerate insertions, and which point mutations allow the mutant protein to function in substantially the same way as the native desaturase. All such mutant proteins and nucleotide sequences encoding them are within the scope of the present invention.

EXPRESSION OF DESATURASE GENES

Once the DNA encoding a desaturase polypeptide has been obtained, it is placed in a vector capable of replication in a host cell, or is propagated *in vitro* by means of techniques such as PCR or long PCR. Replicating vectors can include plasmids, phage, viruses, cosmids and the like. Desirable vectors include those useful for mutagenesis of the gene of interest or for expression of the gene of interest in host cells. The technique of long PCR has made *in vitro* propagation of large constructs possible, so that modifications to the gene of interest, such as mutagenesis or addition of expression signals, and propagation of the resulting constructs can occur entirely *in vitro* without the use of a replicating vector or a host cell.

For expression of a desaturase polypeptide, functional transcriptional and translational initiation and termination regions are operably linked to the DNA encoding the desaturase polypeptide. Expression of the polypeptide coding region can take place *in vitro* or in a host cell. Transcriptional and translational initiation and termination regions are derived from a variety of nonexclusive sources, including the DNA to be expressed, genes known or suspected to be capable of expression in the desired system, expression vectors, chemical synthesis, or from an endogenous locus in a host cell.

Expression In Vitr

In vitro expression can be accomplished, for example, by placing the coding region for the desaturase polypeptide in an expression vector designed for *in vitro* use and adding rabbit reticulocyte lysate and cofactors; labeled amino acids can be incorporated if desired. Such *in vitro* expression vectors may provide some or all of the expression signals necessary in the system used. These methods are well known in the art and the components of the system are commercially available. The reaction mixture can then be assayed directly for the polypeptide, for example by determining its activity, or the synthesized polypeptide can be purified and then assayed.

Expression In A Host Cell

Expression in a host cell can be accomplished in a transient or stable fashion. Transient expression can occur from introduced constructs which contain expression signals functional in the host cell, but which constructs do not replicate and rarely integrate in the host cell, or where the host cell is not proliferating. Transient expression also can be accomplished by inducing the activity of a regulatable promoter operably linked to the gene of interest, although such inducible systems frequently exhibit a low basal level of expression. Stable expression can be achieved by introduction of a construct that can integrate into the host genome or that autonomously replicates in the host cell. Stable expression of the gene of interest can be selected for through the use of a selectable marker located on or transfected with the expression construct, followed by selection for cells expressing the marker. When stable expression results from integration, integration of constructs can occur randomly within the host genome or can be targeted through the use of constructs containing regions of homology with the host genome sufficient to target recombination with the host locus. Where constructs are targeted to an endogenous locus, all or some of the transcriptional and translational regulatory regions can be provided by the endogenous locus.

When increased expression of the desaturase polypeptide in the source organism is desired, several methods can be employed. Additional genes encoding the desaturase polypeptide can be introduced into the host organism. Expression from the native desaturase locus also can be increased through homologous recombination, for example by inserting a stronger promoter into the host genome to cause increased expression, by removing destabilizing sequences from either the mRNA or the encoded protein by deleting that information from the host genome, or by adding stabilizing sequences to the mRNA (USPN 4,910,141).

When it is desirable to express more than one different gene, appropriate regulatory regions and expression methods, introduced genes can be propagated in the host cell through use of replicating vectors or by integration into the host genome. Where two or more genes are expressed from separate replicating vectors, it is desirable that each vector has a different means of replication. Each introduced construct, whether integrated or not, should have a different means of selection and should lack homology to the other constructs to maintain stable expression and prevent reassortment of elements among constructs. Judicious choices of regulatory regions, selection means and method of propagation of the introduced construct can be experimentally determined so that all introduced genes are expressed at the necessary levels to provide for synthesis of the desired products.

As an example, where the host cell is a yeast, transcriptional and translational regions functional in yeast cells are provided, particularly from the host species. The transcriptional initiation regulatory regions can be obtained, for example from genes in the glycolytic pathway, such as alcohol dehydrogenase, glyceraldehyde-3-phosphate dehydrogenase (GPD), phosphoglucoisomerase, phosphoglycerate kinase, etc. or regulatable genes such as acid phosphatase, lactase, metallothionein, glucoamylase, etc. Any one of a number of regulatory sequences can be used in a particular situation, depending upon whether constitutive or induced transcription is desired, the particular efficiency of the promoter in conjunction with the open-reading frame of interest, the ability to join a strong promoter with a control region from a

different promoter which allows for inducible transcription, ease f construction, and the like. Of particular interest are promoters which are activated in the presence of galactose. Galactose-inducible promoters (GAL1, GAL7, and GAL10) have been extensively utilized for high level and regulated expression of protein in yeast (Lue *et al.*, *Mol. Cell. Biol.* Vol. 7, p. 3446, 1987; Johnston, *Microbiol. Rev.* Vol. 51, p. 458, 1987). Transcription from the GAL promoters is activated by the GAL4 protein, which binds to the promoter region and activates transcription when galactose is present. In the absence of galactose, the antagonist GAL80 binds to GAL4 and prevents GAL4 from activating transcription. Addition of galactose prevents GAL80 from inhibiting activation by GAL4.

Nucleotide sequences surrounding the translational initiation codon ATG have been found to affect expression in yeast cells. If the desired polypeptide is poorly expressed in yeast, the nucleotide sequences of exogenous genes can be modified to include an efficient yeast translation initiation sequence to obtain optimal gene expression. For expression in *Saccharomyces*, this can be done by site-directed mutagenesis of an inefficiently expressed gene by fusing it in-frame to an endogenous *Saccharomyces* gene, preferably a highly expressed gene, such as the lactase gene.

The termination region can be derived from the 3' region of the gene from which the initiation region was obtained or from a different gene. A large number of termination regions are known to and have been found to be satisfactory in a variety of hosts from the same and different genera and species. The termination region usually is selected more as a matter of convenience rather than because of any particular property. Preferably, the termination region is derived from a yeast gene, particularly *Saccharomyces*, *Schizosaccharomyces*, *Candida* or *Kluyveromyces*. The 3' regions of two mammalian genes, γ interferon and α2 interferon, are also known to function in yeast.

INTRODUCTION OF CONSTRUCTS INTO HOST CELLS

Constructs comprising the gene of interest may be introduced into a host cell by standard techniques. These techniques include transformation, protoplast fusion, lipofection, transfection, transduction, conjugation, infection, bolistic impact, electroporation, microinjection, scraping, or any other method which introduces the gene of interest into the host cell. Methods of transformation which are used include lithium acetate transformation (*Methods in Enzymology*, Vol. 194, p. 186-187, 1991). For convenience, a host cell which has been manipulated by any method to take up a DNA sequence or construct will be referred to as "transformed" or "recombinant" herein.

The subject host will have at least have one copy of the expression construct and may have two or more, depending upon whether the gene is integrated into the genome, amplified, or is present on an extrachromosomal element having multiple copy numbers. Where the subject host is a yeast, four principal types of yeast plasmid vectors can be used: Yeast Integrating plasmids (YIps), Yeast Replicating plasmids (YRps), Yeast Centromere plasmids (YCps), and Yeast Episomal plasmids (YEps). YIps lack a yeast replication origin and must be propagated as integrated elements in the yeast genome. YRps have a chromosomally derived autonomously replicating sequence and are propagated as medium copy number (20 to 40), autonomously replicating, unstably segregating plasmids. YCps have both a replication origin and a centromere sequence and propagate as low copy number (10-20), autonomously replicating, stably segregating plasmids. YEps have an origin of replication from the yeast 2μm plasmid and are propagated as high copy number, autonomously replicating, irregularly segregating plasmids. The presence of the plasmids in yeast can be ensured by maintaining selection for a marker on the plasmid. Of particular interest are the yeast vectors pYES2 (a YEp plasmid available from Invitrogen, confers uracil prototrophy and a GAL1 galactose-inducible promoter for expression), pRS425-pG1 (a YEp plasmid obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University, containing a constitutive GPD promoter and conferring leucine prototrophy), and pYX424 (a YEp plasmid having a constitutive TP1 promoter and conferring

leucine prototrophy; Alber, T. and Kawasaki, G. (1982). *J. Mol. & Appl. Genetics* 1: 419).

The transformed host cell can be identified by selection for a marker contained on the introduced construct. Alternatively, a separate marker construct may be introduced with the desired construct, as many transformation techniques introduce many DNA molecules into host cells. Typically, transformed hosts are selected for their ability to grow on selective media. Selective media may incorporate an antibiotic or lack a factor necessary for growth of the untransformed host, such as a nutrient or growth factor. An introduced marker gene therefor may confer antibiotic resistance, or encode an essential growth factor or enzyme, and permit growth on selective media when expressed in the transformed host. Selection of a transformed host can also occur when the expressed marker protein can be detected, either directly or indirectly. The marker protein may be expressed alone or as a fusion to another protein. The marker protein can be detected by its enzymatic activity; for example β galactosidase can convert the substrate X-gal to a colored product, and luciferase can convert luciferin to a light-emitting product. The marker protein can be detected by its light-producing or modifying characteristics; for example, the green fluorescent protein of *Aequorea victoria* fluoresces when illuminated with blue light. Antibodies can be used to detect the marker protein or a molecular tag on, for example, a protein of interest. Cells expressing the marker protein or tag can be selected, for example, visually, or by techniques such as FACS or panning using antibodies. For selection of yeast transformants, any marker that functions in yeast may be used. Desirably, resistance to kanamycin and the amino glycoside G418 are of interest, as well as ability to grow on media lacking uracil, leucine, lysine or tryptophan.

Of particular interest is the Δ6- and Δ12-desaturase-mediated production of PUFAs in prokaryotic and eukaryotic host cells. Prokaryotic cells of interest include *Eschericia*, *Bacillus*, *Lactobacillus*, *cyanobacteria* and the like. Eukaryotic cells include mammalian cells such as those of lactating animals, avian cells such as of chickens, and other cells amenable to genetic manipulation including insect, fungal, and algae cells. The cells may be

cultured or formed as part or all of a host organism including an animal. Viruses and bacteriophage also may be used with the cells in the production of PUFAs, particularly for gene transfer, cellular targeting and selection. In a preferred embodiment, the host is any microorganism or animal which produces and/or can assimilate exogenously supplied substrate(s) for a Δ6- and/or Δ12-desaturase, and preferably produces large amounts of one or more of the substrates. Examples of host animals include mice, rats, rabbits, chickens, quail, turkeys, bovines, sheep, pigs, goats, yaks, etc., which are amenable to genetic manipulation and cloning for rapid expansion of the transgene expressing population. For animals, the desaturase transgene(s) can be adapted for expression in target organelles, tissues and body fluids through modification of the gene regulatory regions. Of particular interest is the production of PUFAs in the breast milk of the host animal.

Expression In Yeast

Examples of host microorganisms include *Saccharomyces cerevisiae*, *Saccharomyces carlsbergensis*, or other yeast such as *Candida, Kluyveromyces* or other fungi, for example, filamentous fungi such as *Aspergillus, Neurospora, Penicillium*, etc. Desirable characteristics of a host microorganism are, for example, that it is genetically well characterized, can be used for high level expression of the product using ultra-high density fermentation, and is on the GRAS (generally recognized as safe) list since the proposed end product is intended for ingestion by humans. Of particular interest is use of a yeast, more particularly baker's yeast (*S. cerevisiae*), as a cell host in the subject invention. Strains of particular interest are SC334 (Mat α pep4-3 prbl-1122 ura3-52 leu2-3, 112 regl-501 gal1; *Gene* 83:57-64, 1989, Hovland P. *et al.*), YTC34 (α ade2-101 his3Δ200 lys2-801 ura3-52; obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University), YTC41 (a/α ura3-52/ura3=52 lys2-801/lys2-801 ade2-101/ade2-101 trp1-Δ1/trp1-Δ1 his3Δ200/his3Δ200 leu2Δ1/leu2Δ1; obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University), BJ1995 (obtained from the Yeast Genetic

Stock Centre, 1021 Donner Laboratory, Berkeley, CA 94720), INVSC1 (Mat α hiw3Δ1 leu2 trp1-289 ura3-52; obtained from Invitrogen, 1600 Faraday Ave., Carlsbad, CA 92008) and INVSC2 (Mat α his3Δ200 ura3-167; obtained from Invitrogen).

Expression in Avian Species

For producing PUFAs in avian species and cells, such as chickens, turkeys, quail and ducks, gene transfer can be performed by introducing a nucleic acid sequence encoding a Δ6 and/or Δ12-desaturase into the cells following procedures known in the art. If a transgenic animal is desired, pluripotent stem cells of embryos can be provided with a vector carrying a desaturase encoding transgene and developed into adult animal (USPN 5,162,215; Ono *et al.* (1996) *Comparative Biochemistry and Physiology A 113*(3):287-292; WO 9612793; WO 9606160). In most cases, the transgene will be modified to express high levels of the desaturase in order to increase production of PUFAs. The transgene can be modified, for example, by providing transcriptional and/or translational regulatory regions that function in avian cells, such as promoters which direct expression in particular tissues and egg parts such as yolk. The gene regulatory regions can be obtained from a variety of sources, including chicken anemia or avian leukosis viruses or avian genes such as a chicken ovalbumin gene.

Expression in Insect Cells

Production of PUFAs in insect cells can be conducted using baculovirus expression vectors harboring one or more desaturase transgenes. Baculovirus expression vectors are available from several commercial sources such as Clonetech. Methods for producing hybrid and transgenic strains of algae, such as marine algae, which contain and express a desaturase transgene also are provided. For example, transgenic marine algae may be prepared as described in USPN 5,426,040. As with the other expression systems described above, the timing, extent of expression and activity of the desaturase transgene can be

regulated by fitting the polypeptide coding sequence with the appropriate transcriptional and translational regulatory regions selected for a particular use. Of particular interest are promoter regions which can be induced under preselected growth conditions. For example, introduction of temperature sensitive and/or metabolite responsive mutations into the desaturase transgene coding sequences, its regulatory regions, and/or the genome of cells into which the transgene is introduced can be used for this purpose.

The transformed host cell is grown under appropriate conditions adapted for a desired end result. For host cells grown in culture, the conditions are typically optimized to produce the greatest or most economical yield of PUFAs, which relates to the selected desaturase activity. Media conditions which may be optimized include: carbon source, nitrogen source, addition of substrate, final concentration of added substrate, form of substrate added, aerobic or anaerobic growth, growth temperature, inducing agent, induction temperature, growth phase at induction, growth phase at harvest, pH, density, and maintenance of selection. Microorganisms of interest, such as yeast are preferably grown in selected medium. For yeast, complex media such as peptone broth (YPD) or a defined media such as a minimal media (contains amino acids, yeast nitrogen base, and ammonium sulfate, and lacks a component for selection, for example uracil) are preferred. Desirably, substrates to be added are first dissolved in ethanol. Where necessary, expression of the polypeptide of interest may be induced, for example by including or adding galactose to induce expression from a GAL promoter.

Expression In Plants

Production of PUFA's in plants can be conducted using various plant transformation systems such as the use of *Agrobacterium tumefaciens*, plant viruses, particle cell transformation and the like which are disclosed in Applicant's related applications U.S. Application Serial Nos. 08/834,033 and 08/956,985 and continuation-in-part applications filed simultaneously with this application all of which are hereby incorporated by reference.

Expression In An Animal

Expression in cells of a host animal can likewise be accomplished in a transient or stable manner. Transient expression can be accomplished via known methods, for example infection or lipofection, and can be repeated in order to maintain desired expression levels of the introduced construct (*see* Ebert, PCT publication WO 94/05782). Stable expression can be accomplished via integration of a construct into the host genome, resulting in a transgenic animal. The construct can be introduced, for example, by microinjection of the construct into the pronuclei of a fertilized egg, or by transfection, retroviral infection or other techniques whereby the construct is introduced into a cell line which may form or be incorporated into an adult animal (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Willmut *et al* (1997) Nature 385:810). The recombinant eggs or embryos are transferred to a surrogate mother (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Wilmut *et al* (supra)).

After birth, transgenic animals are identified, for example, by the presence of an introduced marker gene, such as for coat color, or by PCR or Southern blotting from a blood, milk or tissue sample to detect the introduced construct, or by an immunological or enzymological assay to detect the expressed protein or the products produced therefrom (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Wilmut *et al* (supra)). The resulting transgenic animals may be entirely transgenic or may be mosaics, having the transgenes in only a subset of their cells. The advent of mammalian cloning, accomplished by fusing a nucleated cell with an enucleated egg, followed by transfer into a surrogate mother, presents the possibility of rapid, large-scale production upon obtaining a "founder" animal or cell comprising the introduced construct; prior to this, it was necessary for the transgene to be present in the germ line of the animal for propagation (Wilmut *et al* (supra)).

Expression in a host animal presents certain efficiencies, particularly where the host is a domesticated animal. For production of PUFAs in a fluid readily obtainable from the host animal, such as milk, the desaturase transgene can be expressed in mammary cells from a female host, and the PUFA content of the host cells altered. The desaturase transgene can be adapted for expression so that it is retained in the mammary cells, or secreted into milk, to form the PUFA reaction products localized to the milk (PCT publication WO 95/24488). Expression can be targeted for expression in mammary tissue using specific regulatory sequences, such as those of bovine α-lactalbumin, α-casein, β-casein, γ-casein, κ-casein, β-lactoglobulin, or whey acidic protein, and may optionally include one or more introns and/or secretory signal sequences (U.S. Patent No. 5,530,177; Rosen, U.S. Patent No. 5,565,362; Clark *et al.*, U.S. Patent No. 5,366,894; Garner *et al.*, PCT publication WO 95/23868). Expression of desaturase transgenes, or antisense desaturase transcripts, adapted in this manner can be used to alter the levels of specific PUFAs, or derivatives thereof, found in the animals milk. Additionally, the desaturase transgene(s) can be expressed either by itself or with other transgenes, in order to produce animal milk containing higher proportions of desired PUFAs or PUFA ratios and concentrations that resemble human breast milk (Prieto *et al.*, PCT publication WO 95/24494).

PURIFICATION OF FATTY ACIDS

The desaturated fatty acids may be found in the host microorganism or animal as free fatty acids or in conjugated forms such as acylglycerols, phospholipids, sulfolipids or glycolipids, and may be extracted from the host cell through a variety of means well-known in the art. Such means may include extraction with organic solvents, sonication, supercritical fluid extraction using for example carbon dioxide, and physical means such as presses, or combinations thereof. Of particular interest is extraction with hexane or methanol and chloroform. Where desirable, the aqueous layer can be acidified to protonate negatively charged moieties and thereby increase partitioning of desired products into the organic layer. After extraction, the organic solvents can be removed by evaporation under a stream of nitrogen. When isolated in

conjugated forms, the products may be enzymatically or chemically cleaved to release the free fatty acid or a less complex conjugate of interest, and can then be subject to further manipulations to produce a desired end product. Desirably, conjugated forms of fatty acids are cleaved with potassium hydroxide.

If further purification is necessary, standard methods can be employed. Such methods may include extraction, treatment with urea, fractional crystallization, HPLC, fractional distillation, silica gel chromatography, high speed centrifugation or distillation, or combinations of these techniques. Protection of reactive groups, such as the acid or alkenyl groups, may be done at any step through known techniques, for example alkylation or iodination. Methods used include methylation of the fatty acids to produce methyl esters. Similarly, protecting groups may be removed at any step. Desirably, purification of fractions containing GLA, SDA, ARA, DHA and EPA may be accomplished by treatment with urea and/or fractional distillation.

USES OF FATTY ACIDS

The fatty acids of the subject invention finds many applications. Probes based on the DNAs of the present invention may find use in methods for isolating related molecules or in methods to detect organisms expressing desaturases. When used as probes, the DNAs or oligonucleotides must be detectable. This is usually accomplished by attaching a label either at an internal site, for example via incorporation of a modified residue, or at the 5' or 3' terminus. Such labels can be directly detectable, can bind to a secondary molecule that is detectably labeled, or can bind to an unlabelled secondary molecule and a detectably labeled tertiary molecule; this process can be extended as long as is practical to achieve a satisfactorily detectable signal without unacceptable levels of background signal. Secondary, tertiary, or bridging systems can include use of antibodies directed against any other molecule, including labels or other antibodies, or can involve any molecules which bind to each other, for example a biotin-streptavidin/avidin system. Detectable labels typically include radioactive isotopes, molecules which chemically or enzymatically produce or alter light, enzymes which produce

detectable reaction products, magnetic molecules, fluorescent m lecules or molecules whose fluorescence or light-emitting characteristics change upon binding. Examples of labelling methods can be found in USPN 5,011,770. Alternatively, the binding of target molecules can be directly detected by measuring the change in heat of solution on binding of probe to target via isothermal titration calorimetry, or by coating the probe or target on a surface and detecting the change in scattering of light from the surface produced by binding of target or probe, respectively, as may be done with the BIAcore system.

PUFAs produced by recombinant means find applications in a wide variety of areas. Supplementation of animals or humans with PUFAs in various forms can result in increased levels not only of the added PUFAs but of their metabolic progeny as well.

NUTRITIONAL COMPOSITIONS

The present invention also includes nutritional compositions. Such compositions, for purposes of the present invention, include any food or preparation for human consumption including for enteral or parenteral consumption, which when taken into the body (a) serve to nourish or build up tissues or supply energy and/or (b) maintain, restore or support adequate nutritional status or metabolic function.

The nutritional composition of the present invention comprises at least one oil or acid produced in accordance with the present invention and may either be in a solid or liquid form. Additionally, the composition may include edible macronutrients, vitamins and minerals in amounts desired for a particular use. The amount of such ingredients will vary depending on whether the composition is intended for use with normal, healthy infants, children or adults having specialized needs such as those which accompany certain metabolic conditions (e.g., metabolic disorders).

Examples of macronutrients which may be added to the composition include but are not limited to edible fats, carbohydrates and proteins. Examples of such edible fats include but are not limited to coconut oil, soy oil, and mono-

and diglycerides. Examples of such carbohydrates include but are not limited to glucose, edible lactose and hydrolyzed search. Additionally, examples of proteins which may be utilized in the nutritional composition of the invention include but are not limited to soy proteins, electrodialysed whey , electrodialysed skim milk, milk whey, or the hydrolysates of these proteins.

With respect to vitamins and minerals, the following may be added to the nutritional compositions of the present invention: calcium, phosphorus, potassium, sodium, chloride, magnesium, manganese, iron, copper, zinc, selenium, iodine, and Vitamins A, E, D, C, and the B complex. Other such vitamins and minerals may also be added.

The components utilized in the nutritional compositions of the present invention will of semi-purified or purified origin. By semi-purified or purified is meant a material which has been prepared by purification of a natural material or by synthesis.

Examples of nutritional compositions of the present invention include but are not limited to infant formulas, dietary supplements, and rehydration compositions. Nutritional compositions of particular interest include but are not limited to those utilized for enteral and parenteral supplementation for infants, specialist infant formulae, supplements for the elderly, and supplements for those with gastrointestinal difficulties and/or malabsorption.

Nutritional Compositions

A typical nutritional composition of the present invention will contain edible macronutrients, vitamins and minerals in amounts desired for a particular use. The amounts of such ingredients will vary depending on whether the formulation is intended for use with normal, healthy individuals temporarily exposed to stress, or to subjects having specialized needs due to certain chronic or acute disease states (e.g., metabolic disorders). It will be understood by persons skilled in the art that the components utilized in a nutritional formulation of the present invention are of semi-purified or purified origin. By semi-purified or purified is meant a material that has been prepared by

purification of a natural material or by synthesis. These techniques are well known in the art (See, e.g., Code of Federal Regulations for Food Ingredients and Food Processing; Recommended Dietary Allowances, 10th Ed., National Academy Press, Washington, D.C., 1989).

In a preferred embodiment, a nutritional formulation of the present invention is an enteral nutritional product, more preferably an adult or child enteral nutritional product. Accordingly in a further aspect of the invention, a nutritional formulation is provided that is suitable for feeding adults or children, who are experiencing stress. The formula comprises, in addition to the PUFAs of the invention; macronutrients, vitamins and minerals in amounts designed to provide the daily nutritional requirements of adults.

The macronutritional components include edible fats, carbohydrates and proteins. Exemplary edible fats are coconut oil, soy oil, and mono- and diglycerides and the PUFA oils of this invention. Exemplary carbohydrates are glucose, edible lactose and hydrolyzed cornstarch. A typical protein source would be soy protein, electrodialysed whey or electrodialysed skim milk or milk whey, or the hydrolysates of these proteins, although other protein sources are also available and may be used. These macronutrients would be added in the form of commonly accepted nutritional compounds in amount equivalent to those present in human milk or an energy basis, i.e., on a per calorie basis.

Methods for formulating liquid and enteral nutritional formulas are well known in the art and are described in detail in the examples.

The enteral formula can be sterilized and subsequently utilized on a ready-to-feed (RTF) basis or stored in a concentrated liquid or a powder. The powder can be prepared by spray drying the enteral formula prepared as indicated above, and the formula can be reconstituted by rehydrating the concentrate. Adult and infant nutritional formulas are well known in the art and commercially available (e.g., Similac®, Ensure®, Jevity® and Alimentum® from Ross Products Division, Abbott Laboratories). An oil or acid of the present invention can be added to any of these formulas in the amounts described below.

The energy density of the nutritional composition when in liquid form, can typically range from about 0.6 to 3.0 Kcal per ml. When in solid or powdered form, the nutritional supplement can contain from about 1.2 to more than 9 Kcals per gm, preferably 3 to 7 Kcals per gm. In general, the osmolality of a liquid product should be less than 700 mOsm and more preferably less than 660 mOsm.

The nutritional formula would typically include vitamins and minerals, in addition to the PUFAs of the invention, in order to help the individual ingest the minimum daily requirements for these substances. In addition to the PUFAs listed above, it may also be desirable to supplement the nutritional composition with zinc, copper, and folic acid in addition to antioxidants. It is believed that these substances will also provide a boost to the stressed immune system and thus will provide further benefits to the individual. The presence of zinc, copper or folic acid is optional and is not required in order to gain the beneficial effects on immune suppression. Likewise a pharmaceutical composition can be supplemented with these same substances as well.

In a more preferred embodiment, the nutritional contains, in addition to the antioxidant system and the PUFA component, a source of carbohydrate wherein at least 5 weight % of said carbohydrate is an indigestible oligosaccharide. In yet a more preferred embodiment, the nutritional composition additionally contains protein, taurine and carnitine.

The PUFAs, or derivatives thereof, made by the disclosed method can be used as dietary substitutes, or supplements, particularly infant formulas, for patients undergoing intravenous feeding or for preventing or treating malnutrition. Typically, human breast milk has a fatty acid profile comprising from about 0.15 % to about 0.36 % as DHA, from about 0.03 % to about 0.13 % as EPA, from about 0.30 % to about 0.88 % as ARA, from about 0.22 % to about 0.67 % as DGLA, and from about 0.27 % to about 1.04 % as GLA. Additionally, the predominant triglyceride in human milk has been reported to be 1,3-di-oleoyl-2-palmitoyl, with 2-palmitoyl glycerides reported as better absorbed than 2-oleoyl or 2-lineoyl glycerides (USPN 4,876,107). Thus, fatty acids such as ARA, DGLA, GLA and/or EPA produced by the invention can be

used to alter the composition of infant formulas to better replicate the PUFA composition of human breast milk. In particular, an oil composition for use in a pharmacologic or food supplement, particularly a breast milk substitute or supplement, will preferably comprise one or more of ARA, DGLA and GLA. More preferably the oil will comprise from about 0.3 to 30% ARA, from about 0.2 to 30% DGLA, and from about 0.2 to about 30% GLA.

In addition to the concentration, the ratios of ARA, DGLA and GLA can be adapted for a particular given end use. When formulated as a breast milk supplement or substitute, an oil composition which contains two or more of ARA, DGLA and GLA will be provided in a ratio of about 1:19:30 to about 6:1:0.2, respectively. For example, the breast milk of animals can vary in ratios of ARA:DGLA:DGL ranging from 1:19:30 to 6:1:0.2, which includes intermediate ratios which are preferably about 1:1:1, 1:2:1, 1:1:4. When produced together in a host cell, adjusting the rate and percent of conversion of a precursor substrate such as GLA and DGLA to ARA can be used to precisely control the PUFA ratios. For example, a 5% to 10% conversion rate of DGLA to ARA can be used to produce an ARA to DGLA ratio of about 1:19, whereas a conversion rate of about 75% to 80% can be used to produce an ARA to DGLA ratio of about 6:1. Therefore, whether in a cell culture system or in a host animal, regulating the timing, extent and specificity of desaturase expression as described can be used to modulate the PUFA levels and ratios. Depending on the expression system used, e.g., cell culture or an animal expressing oil(s) in its milk, the oils also can be isolated and recombined in the desired concentrations and ratios. Amounts of oils providing these ratios of PUFA can be determined following standard protocols. PUFAs, or host cells containing them, also can be used as animal food supplements to alter an animal's tissue or milk fatty acid composition to one more desirable for human or animal consumption.

For dietary supplementation, the purified PUFAs, or derivatives thereof, may be incorporated into cooking oils, fats or margarines formulated so that in normal use the recipient would receive the desired amount. The PUFAs may

also be incorporated into infant formulas, nutritional supplements or other food products, and may find use as anti-inflammatory or cholesterol lowering agents.

Pharmaceutical Compositions

The present invention also encompasses a pharmaceutical composition comprising one or more of the acids and/or resulting oils produced in accordance with the methods described herein. More specifically, such a pharmaceutical composition may comprise one or more of the acids and/or oils as well as a standard, well-known, non-toxic pharmaceutically acceptable carrier, adjuvant or vehicle such as, for example, phosphate buffered saline, water, ethanol, polyols, vegetable oils, a wetting agent or an emulsion such as a water/oil emulsion. The composition may be in either a liquid or solid form. For example, the composition may be in the form of a tablet, capsule, ingestible liquid or powder, injectible, or topical ointment or cream.

Possible routes of administration include, for example, oral, rectal and parenteral. The route of administration will, of course, depend upon the desired effect. For example, if the composition is being utilized to treat rough, dry, or aging skin, to treat injured or burned skin, or to treat skin or hair affected by a disease or condition, it may perhaps be applied topically.

The dosage of the composition to be administered to the patient may be determined by one of ordinary skill in the art and depends upon various factors such as weight of the patient, age of the patient, immune status of the patient, etc.

With respect to form, the composition may be, for example, a solution, a dispersion, a suspension, an emulsion or a sterile powder which is then reconstituted.

Additionally, the composition of the present invention may be utilized for cosmetic purposes. It may be added to pre-existing cosmetic compositions such that a mixture is formed or may be used as a sole composition.

Pharmaceutical compositions may be utilized to administer the PUFA component to an individual. Suitable pharmaceutical compositions may comprise physiologically acceptable sterile aqueous or non-aqueous solutions, dispersions, suspensions or emulsions and sterile powders for reconstitution into sterile solutions or dispersions for ingestion. Examples of suitable aqueous and non-aqueous carriers, diluents, solvents or vehicles include water, ethanol, polyols (propyleneglycol, polyethyleneglycol, glycerol, and the like), suitable mixtures thereof, vegetable oils (such as olive oil) and injectable organic esters such as ethyl oleate. Proper fluidity can be maintained, for example, by the maintenance of the required particle size in the case of dispersions and by the use of surfactants. It may also be desirable to include isotonic agents, for example sugars, sodium chloride and the like. Besides such inert diluents, the composition can also include adjuvants, such as wetting agents, emulsifying and suspending agents, sweetening, flavoring and perfuming agents.

Suspensions, in addition to the active compounds, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth or mixtures of these substances, and the like.

Solid dosage forms such as tablets and capsules can be prepared using techniques well known in the art. For example, PUFAs of the invention can be tableted with conventional tablet bases such as lactose, sucrose, and cornstarch in combination with binders such as acacia, cornstarch or gelatin, disintegrating agents such as potato starch or alginic acid and a lubricant such as stearic acid or magnesium stearate. Capsules can be prepared by incorporating these excipients into a gelatin capsule along with the antioxidants and the PUFA component. The amount of the antioxidants and PUFA component that should be incorporated into the pharmaceutical formulation should fit within the guidelines discussed above.

As used in this application, the term "treat" refers to either preventing, or reducing the incidence of, the undesired occurrence. For example, to treat immune suppression refers to either preventing the occurrence of this

suppression or reducing the amount of such suppression. The terms "patient" and "individual" are being used interchangeably and both refer to an animal. The term "animal" as used in this application refers to any warm-blooded mammal including, but not limited to, dogs, humans, monkeys, and apes. As used in the application the term "about" refers to an amount varying from the stated range or number by a reasonable amount depending upon the context of use. Any numerical number or range specified in the specification should be considered to be modified by the term about.

"Dose" and "serving" are used interchangeably and refer to the amount of the nutritional or pharmaceutical composition ingested by the patient in a single setting and designed to deliver effective amounts of the antioxidants and the structured triglyceride. As will be readily apparent to those skilled in the art, a single dose or serving of the liquid nutritional powder should supply the amount of antioxidants and PUFAs discussed above. The amount of the dose or serving should be a volume that a typical adult can consume in one sitting. This amount can vary widely depending upon the age, weight, sex or medical condition of the patient. However as a general guideline, a single serving or dose of a liquid nutritional produce should be considered as encompassing a volume from 100 to 600 ml, more preferably from 125 to 500 ml and most preferably from 125 to 300 ml.

The PUFAs of the present invention may also be added to food even when supplementation of the diet is not required. For example, the composition may be added to food of any type including but not limited to margarines, modified butters, cheeses, milk, yogurt, chocolate, candy, snacks, salad oils, cooking oils, cooking fats, meats, fish and beverages.

<u>Pharmaceutical Applications</u>

For pharmaceutical use (human or veterinary), the compositions are generally administered orally but can be administered by any route by which they may be successfully absorbed, e.g., parenterally (i.e. subcutaneously, intramuscularly or intravenously), rectally or vaginally or topically, for example, as a skin ointment or lotion. The PUFAs of the present invention may

be administered alone or in combination with a pharmaceutically acceptable carrier or excipient. Where available, gelatin capsules are the preferred form of oral administration. Dietary supplementation as set forth above also can provide an oral route of administration. The unsaturated acids of the present invention may be administered in conjugated forms, or as salts, esters, amides or prodrugs of the fatty acids. Any pharmaceutically acceptable salt is encompassed by the present invention; especially preferred are the sodium, potassium or lithium salts. Also encompassed are the N-alkylpolyhydroxamine salts, such as N-methyl glucamine, found in PCT publication WO 96/33155. The preferred esters are the ethyl esters. As solid salts, the PUFAs also can be administered in tablet form. For intravenous administration, the PUFAs or derivatives thereof may be incorporated into commercial formulations such as Intralipids. The typical normal adult plasma fatty acid profile comprises 6.64 to 9.46% of ARA, 1.45 to 3.11% of DGLA, and 0.02 to 0.08% of GLA. These PUFAs or their metabolic precursors can be administered, either alone or in mixtures with other PUFAs, to achieve a normal fatty acid profile in a patient. Where desired, the individual components of formulations may be individually provided in kit form, for single or multiple use. A typical dosage of a particular fatty acid is from 0.1 mg to 20 g, or even 100 g daily, and is preferably from 10 mg to 1, 2, 5 or 10 g daily as required, or molar equivalent amounts of derivative forms thereof. Parenteral nutrition compositions comprising from about 2 to about 30 weight percent fatty acids calculated as triglycerides are encompassed by the present invention; preferred is a composition having from about 1 to about 25 weight percent of the total PUFA composition as GLA (USPN 5,196,198). Other vitamins, and particularly fat-soluble vitamins such as vitamin A, D, E and L-carnitine can optionally be included. Where desired, a preservative such as α tocopherol may be added, typically at about 0.1% by weight.

Suitable pharmaceutical compositions may comprise physiologically acceptable sterile aqueous or non-aqueous solutions, dispersions, suspensions or emulsions and sterile powders for reconstitution into sterile injectible solutions or dispersions. Examples of suitable aqueous and non-aqeuous carriers,

diluents, solvents or vehicles include water, ethanol, polyols (propylleneglyol, polyethylenegycol, glycerol, and the like), suitable mixtures thereof, vegetable oils (such as olive oil) and injectable organic esters such as ehyl oleate. Proper fluidity can be maintained, for example, by the maintenance of the required particle size in the case of dispersions and by the use of surfactants. It may also be desirable to include isotonic agents, for example sugars, sodium chloride and the like. Besides such inert diluents, the composition can also include adjuvants, such as wetting agents, emulsifying and suspending agents, sweetening, flavoring and perfuming agents.

Suspensions in addition to the active compounds, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth, or mixtures of these substances and the like.

An especially preferred pharmaceutical composition contains diacetyltartaric acid esters of mono- and diglycerides dissolved in an aqueous medium or solvent. Diacetyltartaric acid esters of mono- and diglycerides have an HLB value of about 9-12 and are significantly more hydrophilic than existing antimicrobial lipids that have HLB values of 2-4. Those existing hydrophobic lipids cannot be formulated into aqueous compositions. As disclosed herein, those lipids can now be solubilized into aqueous media in combination with diacetyltartaric acid esters of mono-and diglycerides. In accordance with this embodiment, diacetyltartaric acid esters of mono- and diglycerides (e.g., DATEM-C12:0) is melted with other active antimicrobial lipids (e.g., 18:2 and 12:0 monoglycerides) and mixed to obtain a homogeneous mixture. Homogeneity allows for increased antimicrobial activity. The mixture can be completely dispersed in water. This is not possible without the addition of diacetyltartaric acid esters of mono- and diglycerides and premixing with other monoglycerides prior to introduction into water. The aqueous composition can then be admixed under sterile conditions with physiologically acceptable diluents, preservatives, buffers or propellants as may be required to form a spray or inhalant.

The present invention also encompasses the treatment of numerous disorders with fatty acids. Supplementation with PUFAs of the present invention can be used to treat restenosis after angioplasty. Symptoms of inflammation, rheumatoid arthritis, and asthma and psoriasis can be treated with the PUFAs of the present invention. Evidence indicates that PUFAs may be involved in calcium metabolism, suggesting that PUFAs of the present invention may be used in the treatment or prevention of osteoporosis and of kidney or urinary tract stones.

The PUFAs of the present invention can be used in the treatment of cancer. Malignant cells have been shown to have altered fatty acid compositions; addition of fatty acids has been shown to slow their growth and cause cell death, and to increase their susceptibility to chemotherapeutic agents. GLA has been shown to cause reexpression on cancer cells of the E-cadherin cellular adhesion molecules, loss of which is associated with aggressive metastasis. Clinical testing of intravenous administration of the water soluble lithium salt of GLA to pancreatic cancer patients produced statistically significant increases in their survival. PUFA supplementation may also be useful for treating cachexia associated with cancer.

The PUFAs of the present invention can also be used to treat diabetes (USPN 4,826,877; Horrobin *et al.*, Am. J. Clin. Nutr. Vol. 57 (Suppl.), 732S-737S). Altered fatty acid metabolism and composition has been demonstrated in diabetic animals. These alterations have been suggested to be involved in some of the long-term complications resulting from diabetes, including retinopathy, neuropathy, nephropathy and reproductive system damage. Primrose oil, which contains GLA, has been shown to prevent and reverse diabetic nerve damage.

The PUFAs of the present invention can be used to treat eczema, reduce blood pressure and improve math scores. Essential fatty acid deficiency has been suggested as being involved in eczema, and studies have shown beneficial effects on eczema from treatment with GLA. GLA has also been shown to reduce increases in blood pressure associated with stress, and to improve performance on arithmetic tests. GLA and DGLA have been shown to inhibit

platelet aggregation, cause vasodilation, lower cholesterol levels and inhibit proliferation of vessel wall smooth muscle and fibrous tissue (Brenner *et al.*, Adv. Exp. Med. Biol. Vol. 83, p. 85-101, 1976). Administration of GLA or DGLA, alone or in combination with EPA, has been shown to reduce or prevent gastro-intestinal bleeding and other side effects caused by non-steroidal anti-inflammatory drugs (USPN 4,666,701). GLA and DGLA have also been shown to prevent or treat endometriosis and premenstrual syndrome (USPN 4,758,592) and to treat myalgic encephalomyelitis and chronic fatigue after viral infections (USPN 5,116,871).

Further uses of the PUFAs of this invention include use in treatment of AIDS, multiple schlerosis, acute respiratory syndrome, hypertension and inflammatory skin disorders. The PUFAs of the inventions also can be used for formulas for general health as well as for geriatric treatments.

Veterinary Applications

It should be noted that the above-described pharmaceutical and nutritional compositions may be utilized in connection with animals, as well as humans, as animals experience many of the same needs and conditions as human. For example, the oil or acids of the present invention may be utilized in animal feed supplements.

The following examples are presented by way of illustration, not of limitation.

Examples

Example 1	Construction of a cDNA Library from *Mortierella alpina*
Example 2	Isolation of a Δ6-desaturase Nucleotide Sequence from *Mortierella alpina*
Example 3	Identification of Δ6-desaturases Homologous to the *Mortierella alpina* Δ6-desaturase
Example 4	Isolation of a Δ12-desaturase Nucleotide Sequence from *Mortierella Alpina*

Example 5	Expression of *M. alpina* Desaturase Clones in Baker's Yeast
Example 6	Initial Optimization of Culture Conditions
Example 7	Distribution of PUFAs in Yeast Lipid Fractions
Example 8	Further Culture Optimization and Coexpression of Δ6 and Δ12-desaturases
Example 9	Identification of Homologues to *M. alpina* Δ5 and Δ6 desaturases
Example 10	Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms
Example 11	Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms
Example 12	Human Desaturase Gene Sequences
Example 13	Nutritional Compositions

Example 1

Construction of a cDNA Library from *Mortierella alpina*

Total RNA was isolated from a 3 day old PUFA-producing culture of *Mortierella alpina* using the protocol of Hoge *et al.* (1982) *Experimental Mycology* 6:225-232. The RNA was used to prepare double-stranded cDNA using BRL's lambda-ZipLox system following the manufactures instructions. Several size fractions of the *M. alpina* cDNA were packaged separately to yield libraries with different average-sized inserts. A "full-length" library contains approximately 3 x 10^6 clones with an average insert size of 1.77 kb. The "sequencing-grade" library contains approximately 6 x 10^5 clones with an average insert size of 1.1 kb.

Example 2

Isolation of a Δ6-desaturase Nucleotide Sequence from *Mortierella Alpina*

A nucleic acid sequence from a partial cDNA clone, Ma524, encoding a Δ6 fatty acid desaturase from *Mortierella alpina* was obtained by random sequencing of clones from the *M. alpina* cDNA sequencing grade library described in Example 1. cDNA-containing plasmids were excised as follows:

Five µl of phage were combined with 100 µl of *E. coli* DH10B(ZIP) grown in ECLB plus 10 µg/ml kanamycin, 0.2% maltose, and 10 mM $MgSO_4$ and incubated at 37 degrees for 15 minutes. 0.9 ml SOC was added and 100 µl of the bacteria immediately plated on each of 10 ECLB + 50 µg Pen plates. No 45 minute recovery time was needed. The plates were incubated overnight at 37°. Colonies were picked into ECLB + 50 µg Pen media for overnight cultures to be used for making glycerol stocks and miniprep DNA. An aliquot of the culture used for the miniprep is stored as a glycerol stock. Plating on ECLB + 50 µg Pen/ml resulted in more colonies and a greater proportion of colonies containing inserts than plating on 100 µg/ml Pen.

Random colonies were picked and plasmid DNA purified using Qiagen miniprep kits. DNA sequence was obtained from the 5' end of the cDNA insert and compared to the National Center for Biotechnology Information (NCBI) nonredundant database using the BLASTX algorithm. Ma524 was identified as a putative desaturase based on DNA sequence homology to previously identified desaturases.

A full-length cDNA clone was isolated from the *M. alpina* full-length library and designed pCGN5532. The cDNA is contained as a 1617 bp insert in the vector pZL1 (BRL) and, beginning with the first ATG, contains an open reading frame encoding 457 amino acids. The three conserved "histidine boxes" known to be conserved among membrane-bound deaturases (Okuley, et al. (1994) *The Plant Cell* 6:147-158) were found to be present at amino acid positions 172-176, 209-213, and 395-399 (see Figure 3). As with other

membrane-bound Δ6-desaturases the final HXXHH histidine box motif was found to be QXXHH. The amino acid sequence of Ma524 was found to display significant homology to a portion of a *Caenorhabditis elegans* cosmid, WO6D2.4, a cytochrome b5/desaturase fusion protein from sunflower, and the *Synechocystis* and *Spirulina* Δ 6-desaturases. In addition, Ma524 was shown to have homology to the borage Δ6-desaturase amino sequence (PCT publication W) 96/21022). Ma524 thus appears to encode a Δ6-desaturase that is related to the borage and algal Δ6-desaturases. The peptide sequences are shown as SEQ ID NO:5 - SEQ ID NO:11.

The amino terminus of the encoded protein was found to exhibit significant homology to cytochrome b5 proteins. The *Mortierella* cDNA clone appears to represent a fusion between a cytochrome b5 and a fatty acid desaturase. Since cytochrome b5 is believed to function as the electron donor for membrane-bound desaturase enzymes, it is possible that the N-terminal cytochrome b5 domain of this desaturase protein is involved in its function. This may be advantageous when expressing the desaturase in heterologous systems for PUFA production. However, it should be noted that, although the amino acid sequences of Ma524 and the borage Δ6 were found to contain regions of homology, the base compositions of the cDNAs were shown to be significantly different. For example, the borage cDNA was shown to have an overall base composition of 60 % A/T, with some regions exceeding 70 %, while Ma524 was shown to have an average of 44 % A/T base composition, with no regions exceeding 60 %. This may have implications for expressing the cDNAs in microorganisms or animals which favor different base compositions. It is known that poor expression of recombinant genes can occur when the host prefers a base composition different from that of the introduced gene. Mechanisms for such poor expression include decreased stability, cryptic splice sites, and/or translatability of the mRNA and the like.

Example 3

Identification of Δ6-desaturases Homologous to the *Mortierella alpina* Δ6-desaturase

Nucleic acid sequences that encode putative Δ6-desaturases were identified through a BLASTX search of the Expressed Sequence Tag ("EST") databases through NCBI using the Ma524 amino acid sequence. Several sequences showed significant homology. In particular, the deduced amino acid sequence of two *Arabidopsis thaliana* sequences, (accession numbers F13728 and T42806) showed homology to two different regions of the deduced amino acid sequence of Ma524. The following PCR primers were designed: ATTS4723-FOR (complementary to F13728) SEQ ID NO:13
5' CUACUACUACUAGGAGTCCTCTACGGTGTTTTG and
T42806-REV (complementary to T42806) SEQ ID NO:14
5' CAUCAUCAUCAUATGATGCTCAAGCTGAAACTG. Five μg of total RNA isolated from developing siliques of *Arabidopsis thaliana* was reverse transcribed using BRL Superscript RTase and the primer TSyn (5'-CCAAGCTTCTGCAGGAGCTCTTTTTTTTTTTTTTT-3') and is shown as SEQ ID NO:12. PCR was carried out in a 50 ul volume containing: template derived from 25 ng total RNA, 2 pM each primer, 200 μM each deoxyribonucleotide triphosphate, 60 mM Tris-Cl, pH 8.5, 15 mM $(NH_4)_2SO_4$, 2 mM $MgCl_2$, 0.2 U Taq Polymerase. Thermocycler conditions were as follows: 94 degrees for 30 sec., 50 degrees for 30 sec., 72 degrees for 30 sec. PCR was continued for 35 cycles followed by an additional extension at 72 degrees for 7 minutes. PCR resulted in a fragment of approximately ~750 base pairs which was subcloned, named 12-5, and sequenced. Each end of this fragment was formed to correspond to the *Arabidopsis* ESTs from which the PCR primers were designed. The putative amino acid sequence of 12-5 was compared to that of Ma524, and ESTs from human (W28140), mouse (W53753), and *C. elegans* (R05219) (see Figure 4). Homology patterns with the *Mortierella* Δ6- desaturase indicate that these sequences represent putative

desaturase polypeptides. Based on this experiment approach, it is likely that the full-length genes can be cloned using probes based on the EST sequences. Following the cloning, the genes can then be placed into expression vectors, expressed in host cells, and their specific Δ6- or other desaturase activity can be determined as described below.

Example 4

Isolation of a Δ12-desaturase Nucleotide Sequence from *Mortierella alpina*

Based on the fatty acids it accumulates, it seemed probable that *Mortierella alpina* has an ω6 type desaturase. The ω6-desaturase is responsible for the production of linoleic acid (18:2) from oleic acid (18:1). Linoleic acid (18:2) is a substrate for a Δ6-desaturase. This experiment was designed to determine if *Mortierella alpina* has a Δ12-desaturase polypeptide, and if so, to identify the corresponding nucleotide sequence.

A random colony from the *M. alpina* sequencing grade library, Ma648, was sequenced and identified as a putative desaturase based on DNA sequence homology to previously identified desaturases, as described for Ma524 (*see* Example 2). The nucleotide sequence is shown in SEQ ID NO:13. The peptide sequence is shown in SEQ ID NO:4. The deduced amino acid sequence from the 5' end of the Ma648 cDNA displays significant homology to soybean microsomal ω6 (Δ12) desaturase (accession #L43921) as well as castor bean oleate 12-hydroxylase (accession #U22378). In addition, homology was observed when compared to a variety of other ω6 (Δ12) and ω3 (Δ15) fatty acid desaturase sequences.

Example 5

Expression of *M. alpina* Desaturase Clones in Baker's Yeast

Yeast Transformation

Lithium acetate transformation of yeast was performed according to standard protocols (*Methods in Enzymology*, Vol. 194, p. 186-187, 1991). Briefly, yeast were grown in YPD at 30°C. Cells were spun down, resuspended in TE, spun down again, resuspended in TE containing 100 mM lithium acetate, spun down again, and resuspended in TE/lithium acetate. The resuspended yeast were incubated at 30°C for 60 minutes with shaking. Carrier DNA was added, and the yeast were aliquoted into tubes. Transforming DNA was added, and the tubes were incubated for 30 min. at 30°C. PEG solution (35% (w/v) PEG 4000, 100 mM lithium acetate, TE pH7.5) was added followed by a 50 min. incubation at 30°C. A 5 min. heat shock at 42°C was performed, the cells were pelleted, washed with TE, pelleted again and resuspended in TE. The resuspended cells were then plated on selective media.

Desaturase Expression in Transformed Yeast

cDNA clones from *Mortierella alpina* were screened for desaturase activity in baker's yeast. A canola Δ15-desaturase (obtained by PCR using 1st strand cDNA from *Brassica napus* cultivar 212/86 seeds using primers based on the published sequence (Arondel *et al. Science* 258:1353-1355)) was used as a positive control. The Δ15-desaturase gene and the gene from cDNA clones Ma524 and Ma648 were put in the expression vector pYES2 (Invitrogen), resulting in plasmids pCGR-2, pCGR-5 and pCGR-7, respectively. These plasmids were transfected into *S. cerevisiae* yeast strain 334 and expressed after induction with galactose and in the presence of substrates that allowed detection of specific desaturase activity. The control strain was *S. cerevisiae* strain 334 containing the unaltered pYES2 vector. The substrates used, the products produced and the indicated desaturase activity were: DGLA (conversion to ARA would indicate Δ5-desaturase activity), linoleic acid (conversion to GLA

would indicate Δ6-desaturase activity; conversion to ALA would indicate Δ15-desaturase activity), oleic acid (an endogenous substrate made by *S. cerevisiae*, conversion to linoleic acid would indicate Δ12-desaturase activity, which *S. cerevisiae* lacks), or ARA (conversion to EPA would indicate Δ17-desaturase activity).

Cultures were grown for 48-52 hours at 15°C in the presence of a particular substrate. Lipid fractions were extracted for analysis as follows: Cells were pelleted by centrifugation, washed once with sterile ddH_20, and repelleted. Pellets were vortexed with methanol; chloroform was added along with tritridecanoin (as an internal standard). The mixtures were incubated for at least one hour at room temperature or at 4°C overnight. The chloroform layer was extracted and filtered through a Whatman filter with one gram of anhydrous sodium sulfate to remove particulates and residual water. The organic solvents were evaporated at 40°C under a stream of nitrogen. The extracted lipids were then derivatized to fatty acid methyl esters (FAME) for gas chromatography analysis (GC) by adding 2 ml of 0.5 N potassium hydroxide in methanol to a closed tube. The samples were heated to 95°C to 100°C for 30 minutes and cooled to room temperature. Approximately 2 ml of 14 % boron trifluoride in methanol was added and the heating repeated. After the extracted lipid mixture cooled, 2 ml of water and 1 ml of hexane were added to extract the FAME for analysis by GC. The percent conversion was calculated by dividing the product produced by the sum of (the product produced and the substrate added) and then multiplying by 100. To calculate the oleic acid percent conversion, as no substrate was added, the total linoleic acid produced was divided by the sum of oleic acid and linoleic acid produced, then multiplying by 100. The desaturase activity results are provided in Table 1 below.

Table 1

M. alpina Desaturase Expression in Baker's Yeast

CLONE	ENZYME ACTIVITY	% CONVERSION OF SUBSTRATE
pCGR-2	Δ6	0 (18:2 to 18:3w6)
(canola Δ15	Δ15	16.3 (18:2 to 18:3w3)
desaturase)	Δ5	2.0 (20:3 to 20:4w6)
	Δ17	2.8 (20:4 to 20:5w3)
	Δ12	1.8 (18:1 to 18:2w6)
pCGR-5	Δ6	6.0
(M. alpina	Δ15	0
Ma524	Δ5	2.1
	Δ17	0
	Δ12	3.3
pCGR-7	Δ6	0
(M. alpina	Δ15	3.8
Ma648	Δ5	2.2
	Δ17	0
	Δ12	63.4

The Δ15-desaturase control clone exhibited 16.3% conversion of the substrate. The pCGR-5 clone expressing the Ma524 cDNA showed 6% conversion of the substrate to GLA, indicating that the gene encodes a Δ6-desaturase. The pCGR-7 clone expressing the Ma648 cDNA converted 63.4% conversion of the substrate to LA, indicating that the gene encodes a Δ12-desaturase. The background (non-specific conversion of substrate) was between 0-3% in these cases. We also found substrate inhibition of the activity by using different concentrations of the substrate. When substrate was added to 100 μM, the percent conversion to product dropped compared to when substrate was added to 25 μM (see below). Additionally, by varying the substrate concentration between 5 μM and 200 μM, conversion ratios were found to range between about

5% to about 75% greater. These data show that desaturases with different substrate specificities can be expressed in a heterologous system and used to produce poly-unsaturated long chain fatty acids.

Table 2 represents fatty acids of interest as a percent of the total lipid extracted from the yeast host *S. cerevisiae* 334 with the indicated plasmid. No glucose was present in the growth media. Affinity gas chromatography was used to separate the respective lipids. GC/MS was employed to verify the identity of the product(s). The expected product for the *B. napus* Δ15-desaturase, α-linolenic acid, was detected when its substrate, linoleic acid, was added exogenously to the induced yeast culture. This finding demonstrates that yeast expression of a desaturase gene can produce functional enzyme and detectable amounts of product under the current growth conditions. Both exogenously added substrates were taken up by yeast, although slightly less of the longer chain PUFA, dihomo-γ-linolenic acid (20:3), was incorporated into yeast than linoleic acid (18:2) when either was added in free form to the induced yeast cultures. γ-linolenic acid was detected when linoleic acid was present during induction and expression of *S. cerevisiae* 334 (pCGR-5). The presence of this PUFA demonstrates Δ6-desaturase activity from pCGR-5 (MA524). Linoleic acid, identified in the extracted lipids from expression of *S. cerevisiae* 334 (pCGR-7), classifies the cDNA MA648 from *M. alpina* as the Δ12-desaturase.

Example 6

Optimization of Culture Conditions

Table 3A shows the effect of exogenous free fatty acid substrate concentration on yeast uptake and conversion to fatty acid product as a percentage of the total yeast lipid extracted. In all instances, low amounts of exogenous substrate (1-10 μM) resulted in low fatty acid substrate uptake and product formation. Between 25 and 50 μM concentration of free fatty acid in the growth and induction media gave the highest percentage of fatty acid product formed, while the 100 μM concentration and subsequent high uptake into yeast appeared to decrease or inhibit the desaturase activity. The amount of fatty acid substrate for yeast expressing Δ12-desaturase was similar under the same growth conditions, since the substrate, oleic acid, is an endogenous yeast fatty acid. The use of α-linolenic acid as an additional substrate for pCGR-5 (Δ6) produced the expected product, stearidonic acid (Table 3A). The feedback inhibition of high fatty acid substrate concentration was well illustrated when the percent conversion rates of the respective fatty acid substrates to their respective products were compared in Table 3B. In all cases, 100 μM substrate concentration in the growth media decreased the percent conversion to product. The uptake of α-linolenic was comparable to other PUFAs added in free form, while the Δ6-desaturase percent conversion, 3.8-17.5%, to the product stearidonic acid was the lowest of all the substrates examined (Table 3B). The effect of media, such as YPD (rich media) versus minimal media with glucose on the conversion rate of Δ12-desaturase was dramatic. Not only did the conversion rate for oleic to linoleic acid drop, (Table 3B) but the percent of linoleic acid formed also decreased by 11% when rich media was used for growth and induction of yeast desaturase Δ12 expression (Table 3A). The effect of media composition was also evident when glucose was present in the growth media for Δ6-desaturase, since the percent of substrate uptake was decreased at 25 μM (Table 3A). However, the conversion rate remained the

same and percent product formed decreased for Δ6-desaturase for in the presence of glucose.

ND (not done)

Table 4 shows the amount of fatty acid produced by a recombinant desaturase from induced yeast cultures when different amounts of free fatty acid substrate were used. Fatty acid weight was determined since the total amount of lipid varied dramatically when the growth conditions were changed, such as the presence of glucose in the yeast growth and induction media. To better determine the conditions when the recombinant desaturase would produce the most PUFA product, the quantity of individual fatty acids were examined. The absence of glucose dramatically reduced by three fold the amount of linoleic acid produced by recombinant Δ12-desaturase. For the Δ12-desaturase the amount of total yeast lipid was decreased by almost half in the absence of glucose. Conversely, the presence of glucose in the yeast growth media for Δ6-desaturase drops the γ-linolenic acid produced by almost half, while the total amount of yeast lipid produced was not changed by the presence/absence of

glucose. This points to a possible role for glucose as a modulator of Δ6-desaturase activity.

Example 7

Distribution of PUFAs in Yeast Lipid Fractions

Table 5 illustrates the uptake of free fatty acids and their new products formed in yeast lipids as distributed in the major lipid fractions. A total lipid extract was prepared as described above. The lipid extract was separated on TLC plates, and the fractions were identified by comparison to standards. The bands were collected by scraping, and internal standards were added. The fractions were then saponified and methylated as above, and subjected to gas chromatography. The gas chromatograph calculated the amount of fatty acid by comparison to a standard. The phospholipid fraction contained the highest amount of substrate and product PUFAs for Δ6-desaturase activity. It would appear that the substrates are accessible in the phospholipid form to the desaturases.

Table 5

Example 8

Further Culture Optimization and Coexpression of Δ6 and Δ12-desaturases

This experiment was designed to evaluate the growth and induction conditions for optimal activities of desaturases in *Saccharomyces cerevisiae*. A *Saccharomyces cerevisiae* strain (SC334) capable of producing γ-linolenic acid (GLA) was developed, to assess the feasibility of production of PUFA in yeast. The genes for Δ6 and Δ12-desaturases from *M. alpina* were coexpressed in SC334. Expression of Δ12-desaturase converted oleic acid (present in yeast) to linoleic acid. The linoleic acid was used as a substrate by the Δ6-desaturase to produce GLA. The quantity of GLA produced ranged between 5-8% of the total fatty acids produced in SC334 cultures and the conversion rate of linoleic acid to γ-linolenic acid ranged between 30% to 50%. The induction temperature was optimized, and the effect of changing host strain and upstream promoter sequences on expression of Δ6 and Δ12 (MA 524 and MA 648 respectively) desaturase genes was also determined.

Plasmid Construction

The cloning of pCGR5 as well as pCGR7 has been discussed above. To construct pCGR9a and pCGR9b, the Δ6 and Δ12-desaturase genes were amplified using the following sets of primers. The primers pRDS1 and 3 had Xhol site and primers pRDS2 and 4 had Xbal site (indicated in bold). These primer sequences are presented as SEQ ID NO:15-18.

I. Δ6-desaturase amplification primers

a. pRDS1 TAC CAA **CTC GAG** AAA ATG GCT GCT GCT CCC AGT GTG AGG

b. pRDS2 AAC TGA **TCT AGA** TTA CTG CGC CTT ACC CAT CTT GGA GGC

II. Δ12-desaturase amplification primers

a. pRDS3 TAC CAA **CTC GAG** AAA ATG GCA CCT CCC AAC ACT ATC GAT

b. pRDS4 AAC TGA **TCT AGA** TTA CTT CTT GAA AAA GAC CAC GTC TCC

The pCGR5 and pCGR7 constructs were used as template DNA for amplification of Δ6 and Δ12-desaturase genes, respectively. The amplified products were digested with Xbal and Xhol to create "sticky ends". The PCR amplified Δ6-desaturase with Xhol-Xbal ends as cloned into pCGR7, which was also cut with Xho-l-Xbal. This procedure placed the Δ6-desaturase behind the Δ12-desaturase, under the control of an inducible promoter GAL1. This construct was designated pCGR9a. Similarly, to construct pCGR9b, the Δ12-desaturase with XhoI-XbaI ends was cloned in the XhoI-XbaI sites of pCGR5. In pCGR9b the Δ12-desaturase was behind the Δ6-desaturase gene, away from the GAL promoter.

To construct pCGR10, the vector pRS425, which contains the constitutive Glyceraldehyde 3-Phosphate Dehydrogenase (GPD) promoter, was digested with BamHl and pCGR5 was digested with BamHl-Xhol to release the

Δ6-desaturase gene. This Δ6-desaturase fragment and BamHl cut pRS425 were filled using Klenow Polymerase to create blunt ends and ligated, resulting in pCGR10a and pCGR10b containing the Δ6-desaturase gene in the sense and antisense orientation, respectively. To construct pCGR11 and pCGR12, the Δ6 and Δ12-desaturase genes were isolated from pCGR5 and pCGR7, respectively, using an EcoRl-XhoI double digest. The EcoRl-Xhol fragments of Δ6 and Δ12-desaturases were cloned into the pYX242 vector digested with EcoRl-Xhol. The pYX242 vector has the promoter of TPl (a yeast housekeeping gene), which allows constitutive expression.

Yeast Transformation and Expression

Different combinations of pCGR5, pCGR7, pCGR9a, pCGR9b, pCGR10a, pCGR11 and pCGR12 were introduced into various host strains of *Saccharomyces cerevisiae*. Transformation was done using PEG/LiAc protocol (Methods in Enzymology Vol. 194 (1991): 186-187). Transformants were selected by plating on synthetic media lacking the appropriate amino acid. The pCGR5, pCGR7, pCGR9a and pCGR9b can be selected on media lacking uracil. The pCGR10, pCGR11 and pCGR12 constructs can be selected on media lacking leucine. Growth of cultures and fatty acid analysis was performed as in Example 5 above.

Production of GLA

Production of GLA requires the expression of two enzymes (the Δ6 and Δ12-desaturases), which are absent in yeast. To express these enzymes at optimum levels the following constructs or combinations of constructs, were introduced into various host strains:

1) pCGR9a/SC334
2) pCGR9b/SC334
3) pCGR10a and pCGR7/SC334
4) pCGR11 and pCGR7/SC334
5) pCGR12 and pCGR5/SC334

6) pCGR10a and pCGR7/DBY746

7) pCGR10a and pCGR7/DBY746

The pCGR9a construct has both the Δ6 and Δ12-desaturase genes under the control of an inducible GAL promoter. The SC334 host cells transformed with this construct did not show any GLA accumulation in total fatty acids (Fig. 6A and B, lane 1). However, when the Δ6 and Δ12-desaturase genes were individually controlled by the GAL promoter, the control constructs were able to express Δ6- and Δ12-desaturase, as evidenced by the conversion of their respective substrates to products. The Δ12-desaturase gene in pCGR9a was expressed as evidenced by the conversion of 18:1ω9 to 18:2ω6 in pCGR9a/SC334, while the Δ6-desaturase gene was not expressed/active, because the 18:2ω6 was not being converted to 18:3ω6 (Fig. 6A and B, lane 1).

The pCGR9b construct also had both the Δ6 and Δ12-desaturase genes under the control of the GAL promoter but in an inverse order compared to pCGR9a. In this case, very little GLA (<1%) was seen in pCGR9b/SC334 cultures. The expression of Δ12-desaturase was also very low, as evidenced by the low percentage of 18:2ω6 in the total fatty acids (Fig. 6A and B, lane 1).

To test if expressing both enzymes under the control of independent promoters would increase GLA production, the Δ6-desaturase gene was cloned into the pRS425 vector. The construct of pCGR10a has the Δ6-desaturase in the correct orientation, under control of constitutive GPD promoter. The pCGR10b has the Δ6-desaturase gene in the inverse orientation, and serves as the negative control. The pCGR10a/SC334 cells produced significantly higher levels of GLA (5% of the total fatty acids, Fig. 6, lane 3), compared to pCGR9a. Both the Δ6 and Δ12-desaturase genes were expressed at high level because the conversion of 18:1ω9→ 18:2ω6 was 65%, while the conversion of 18:2ω6 → 18:3ω6 (Δ6-desaturase) was 30% (Fig. 6, lane 3). As expected, the negative control pCGR10b/SC334 did not show any GLA.

To further optimize GLA production, the Δ6 and Δ12 genes were introduced into the pYX242 vector, creating pCGR11 and pCGR12

respectively. The pYX242 vector allows for constitutive expression by the TP1 promoter (Alber, T. and Kawasaki, G. (1982). *J. Mol. & Appl. Genetics* 1: 419). The introduction of pCGR11 and pCGR7 in SC334 resulted in approximately 8% of GLA in total fatty acids of SC334. The rate of conversion of 18:1ω9→ 18:2ω6 and 18:2ω6 → 18:3ω6 was approximately 50% and 44% respectively (Fig. 6A and B, lane 4). The presence of pCGR12 and pCGR5 in SC334 resulted in 6.6% GLA in total fatty acids with a conversion rate of approximately 50% for both 18:1ω9 to 18:2ω6 and 18:2ω6 to 18:3ω6, respectively (Fig. 6A and B, lane 5). Thus although the quantity of GLA in total fatty acids was higher in the pCGR11/pCGR7 combination of constructs, the conversion rates of substrate to product were better for the pCGR12/pCGR5 combination.

To determine if changing host strain would increase GLA production, pCGR10a and pCGR7 were introduced into the host strain BJ1995 and DBY746 (obtained from the Yeast Genetic Stock Centre, 1021 Donner Laboratory, Berkeley, CA 94720. The genotype of strain DBY746 is Matα, his3-Δ1, leu2-3, leu2-112, ura3-32, trp1-289, gal). The results are shown in Fig. 7. Changing host strain to BJ1995 did not improve the GLA production, because the quantity of GLA was only 1.31% of total fatty acids and the conversion rate of 18:1ω9 → 18:2ω6 was approximately 17% in BJ1995. No GLA was observed in DBY746 and the conversion of 18:1ω9 → 18:2ω6 was very low (<1% in control) suggesting that a cofactor required for the expression of Δ12-desaturase might be missing in DB746 (Fig. 7, lane 2).

To determine the effect of temperature on GLA production, SC334 cultures containing pCGR10a and pCGR7 were grown at 15°C and 30°C. Higher levels of GLA were found in cultures grown and induced at 15°C than those in cultures grown at 30°C (4.23% vs. 1.68%). This was due to a lower conversion rate of 18:2ω6 → 18:3ω6 at 30°C (11.6% vs. 29% in 15°C) cultures, despite a higher conversion of 18:1ω9 → 18:2ω6 (65% vs. 60% at 30°C (Fig. 8). These results suggest that Δ12- and Δ6-desaturases may have different optimal expression temperatures.

Of the various parameters examined in this study, temperature of growth, yeast host strain and media components had the most significant impact on the expression of desaturase, while timing of substrate addition and concentration of inducer did not significantly affect desaturase expression.

These data show that two DNAs encoding desaturases that can convert LA to GLA or oleic acid to LA can be isolated from *Mortierella alpina* and can be expressed, either individually or in combination, in a heterologous system and used to produce poly-unsaturated long chain fatty acids. Exemplified is the production of GLA from oleic acid by expression of Δ12- and Δ6-desaturases in yeast.

Example 9

Identification of Homologues to *M. alpina* Δ5 and Δ6 desaturases

A nucleic acid sequence that encodes a putative Δ5 desaturase was identified through a TBLASTN search of the expressed sequence tag databases through NCBI using amino acids 100-446 of Ma29 as a query. The truncated portion of the Ma29 sequence was used to avoid picking up homologies based on the cytochrome b5 portion at the N-terminus of the desaturase. The deduced amino acid sequence of an est from *Dictyostelium discoideum* (accession # C25549) shows very significant homology to Ma29 and lesser, but still significant homology to Ma524. The DNA sequence is presented as SEQ ID NO:19. The amino acid sequence is presented as SEQ ID NO:20.

Example 10

Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms

To look for desaturases involved in PUFA production, a cDNA library was constructed from total RNA isolated from *Phaeodactylum tricornutum*. A plasmid-based cDNA librariy was constructed in pSPORT1 (GIBCO-BRL)

following manufacturer's instructions using a commercially available kit (GIBCO-BRL). Random cDNA clones were sequenced and nucleic acid sequences that encode putative Δ5 or Δ6 desaturases were identified through BLAST search of the databases and comparison to Ma29 and Ma524 sequences.

One clone was identified from the *Phaeodactylum* library with homology to Ma29 and Ma524; it is called 144-011-B12. The DNA sequence is presented as SEQ ID NO:21. The amino acid sequence is presented as SEQ ID NO:22.

Example 11

Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms

To look for desaturases involved in PUFA production, a cDNA library was constructed from total RNA isolated from *Schizochytrium* species. A plasmid-based cDNA library was constructed in pSPORT1 (GIBCO-BRL) following manufacturer's instructions using a commercially available kit (GIBCO-BRL). Random cDNA clones were sequenced and nucleic acid sequences that encode putative Δ5 or Δ6 desaturases were identified through BLAST search of the databases and comparison to Ma29 and Ma524 sequences.

One clone was identified from the *Schizochytrium* library with homology to Ma29 and Ma524; it is called 81-23-C7. This clone contains a ~1 kb insert. Partial sequence was obtained from each end of the clone using the universal forward and reverse sequencing primers. The DNA sequence from the forward primer is presented as SEQ ID NO:23. The peptide sequence is presented as SEQ ID NO:24. The DNA sequence from the reverse primer is presented as SEQ ID NO:25. The amino acid sequence from the reverse primer is presented as SEQ ID NO:26.

Example 12

Human Desaturase Gene Sequences

Human desaturase gene sequences potentially involved in long chain polyunsaturated fatty acid biosynthesis were isolated based on homology between the human cDNA sequences and *Mortierella alpina* desaturase gene sequences. The three conserved "histidine boxes" known to be conserved among membrane-bound desaturases were found. As with some other membrane-bound desaturases the final HXXHH histidine box motif was found to be QXXHH. The amino acid sequence of the putative human desaturases exhibited homology to *M. alpina* Δ5, Δ6, Δ9, and Δ12 desaturases.

The *M. alpina* Δ5 desaturase and Δ6 desaturase cDNA sequences were used to search the LifeSeq database of Incyte Pharmaceuticals, Inc., Palo Alto, California 94304. The Δ5 desaturase sequence was divided into fragments; 1) amino acid no. 1-150, 2) amino acid no. 151-300, and 3) amino acid no. 301-446. The Δ6 desaturase sequence was divided into three fragments; 1) amino acid no. 1-150, 2) amino acid no. 151-300, and 3) amino acid no. 301-457. These polypeptide fragments were searched against the database using the "tblastn" algorithm. This alogarithm compares a protein query sequence against a nucleotide sequence database dynamically translated in all six reading frames (both strands).

The polypeptide fragments 2 and 3 of *M. alpina* Δ5 and Δ6 have homologies with the CloneID sequences as outlined in Table 6. The CloneID represents an individual sequence from the Incyte LifeSeq database. After the "tblastn" results have been reviewed, Clone Information was searched with the default settings of Stringency of >=50, and Productscore <=100 for different CloneID numbers. The Clone Information Results displayed the information including the ClusterID, CloneID, Library, HitID, Hit Description. When selected, the ClusterID number displayed the clone information of all the clones that belong in that ClusterID. The Assemble command assembles all of the CloneID which comprise the ClusterID. The following default settings were

used for GCG (Genetics Computer Group, University of Wisconsin Biotechnology Center, Madison, Wisconsin 53705) Assembly:

Word Size:	7
Minimum Overlap:	14
Stringency:	0.8
Minimum Identity:	14
Maximum Gap:	10
Gap Weight:	8
Length Weight:	2

GCG Assembly Results displayed the contigs generated on the basis of sequence information within the CloneID. A contig is an alignment of DNA sequences based on areas of homology among these sequences. A new sequence (consensus sequence) was generated based on the aligned DNA sequences within a contig. The contig containing the CloneID was identified, and the ambiguous sites of the consensus sequence was edited based on the alignment of the CloneIDs (see SEQ ID NO:27 - SEQ ID NO:32) to generate the best possible sequence. The procedure was repeated for all six CloneID listed in Table 6. This produced five unique contigs. The edited consensus sequences of the 5 contigs were imported into the Sequencher software program (Gene Codes Corporation, Ann Arbor, Michigan 48 105). These consensus sequences were assembled. The contig 2511785 overlaps with contig 3506132, and this new contig was called 2535 (SEQ ID NO:33). The contigs from the Sequencher program were copied into the Sequence Analysis software package of GCG.

Each contig was translated in all six reading frames into protein sequences. The *M. alpina* Δ5 (MA29) and Δ6 (MA524) sequences were compared with each of the translated contigs using the FastA search (a Pearson

and Lipman search for similarity between a query sequence and a group of sequences of the same type (nucleic acid or protein)). Homology among these sequences suggest the open reading frames of each contig. The homology among the *M. alpina* Δ5 and Δ6 to contigs 2535 and 3854933 were utilized to create the final contig called 253538a. Figure 13 is the FastA match of the final contig 253538a and MA29, and Figure 14 is the FastA match of the final contig 253538a and MA524. The DNA sequences for the various contigs are presented in SEQ ID NO:27 -SEQ ID NO:33 The various peptide sequences are shown in SEQ ID NO:34 - SEQ ID NO: 40.

Although the open reading frame was generated by merging the two contigs, the contig 2535 shows that there is a unique sequence in the beginning of this contig which does not match with the contig 3854933. Therefore, it is possible that these contigs were generated from independent desaturase like human genes.

The contig 253538a contains an open reading frame encoding 432 amino acids. It starts with Gln (CAG) and ends with the stop codon (TGA). The contig 253538a aligns with both *M. alpina* Δ5 and Δ6 sequences, suggesting that it could be either of the desaturases, as well as other known desaturases which share homology with each other. The individual contigs listed in Table 18, as well as the intermediate contig 2535 and the final contig 253538a can be utilized to isolate the complete genes for human desaturases.

Uses of the human desaturases

These human sequences can be express in yeast and plants utilizing the procedures described in the preceding examples. For expression in mammalian cells transgenic animals, these genes may provide superior codon bias.

In addition, these sequences can be used to isolate related desaturase genes from other organisms.

Table 6

Sections f the Desaturases	Clone ID fr m LifeSeq Database	Keyw rd

151-300 Δ5	3808675	fatty acid desaturase
301-446 Δ5	354535	Δ6
151-300 Δ6	3448789	Δ6
151-300 Δ6	1362863	Δ6
151-300 Δ6	2394760	Δ6
301-457 Δ6	3350263	Δ6

Example 13

I. INFANT FORMULATIONS

A. Isomil® Soy Formula with Iron.

Usage: As a beverage for infants, children and adults with an allergy or sensitivity to cow's milk. A feeding for patients with disorders for which lactose should be avoided: lactase deficiency, lactose intolerance and galactosemia.

Features:

- Soy protein isolate to avoid symptoms of cow's-milk-protein allergy or sensitivity
- Lactose-free formulation to avoid lactose-associated diarrhea
- Low osmolaity (240 mOsm/kg water) to reduce risk of osmotic diarrhea.
- Dual carbohydrates (corn syrup and sucrose) designed to enhance carbohydrate absorption and reduce the risk of exceeding the absorptive capacity of the damaged gut.
- 1.8 mg of Iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.
- Recommended levels of vitamins and minerals.
- Vegetable oils to provide recommended levels of essential fatty acids.
- Milk-white color, milk-like consistency and pleasant aroma.

Ingredients: (Pareve, ®) 85% water, 4.9% corn syrup, 2.6% sugar (sucrose), 2.1% soy oil, 1.9% soy protein isolate, 1.4% coconut oil, 0.15% calcium citrate, 0.11 % calcium phosphate tribasic, potassium citrate, potassium phosphate monobasic, potassium chloride, mono- and disglycerides, soy lecithin, carrageenan, ascorbic acid, L-methionine, magnesium chloride, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

B. Isomil® DF Soy Formula For Diarrhea.

Usage: As a short-term feeding for the dietary management of diarrhea in infants and toddlers.

Features:

- First infant formula to contain added dietary fiber from soy fiber specifically for diarrhea management.
- Clinically shown to reduce the duration of loose, watery stools during mild to severe diarrhea in infants.
- Nutritionally complete to meet the nutritional needs of the infant.
- Soy protein isolate with added L-methionine meets or exceeds an infant's requirement for all essential amino acids.
- Lactose-free formulation to avoid lactose-associated diarrhea.
- Low osmolality (240 mOsm/kg water) to reduce the risk of osmotic diarrhea.
- Dual carbohydrates (corn syrup and sucrose) designed to enhance carbohydrate absorption and reduce the risk of exceeding the absorptive capacity of the damaged gut.

- Meets or exceeds the vitamin and mineral levels recommended by the Committee on Nutrition of the American Academy of Pediatrics and required by the Infant Formula Act.

- 1.8 mg of iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.

- Vegetable oils to provide recommended levels of essential fatty acids.

Ingredients: (Pareve, ®) 86% water, 4.8% corn syrup, 2.5% sugar (sucrose), 2.1% soy oil, 2.0% soy protein isolate, 1.4% coconut oil, 0.77% soy fiber, 0.12% calcium citrate, 0.11 % calcium phosphate tribasic, 0.10% potassium citrate, potassium chloride, potassium phosphate monobasic, mono- and disglycerides, soy lecithin, carrageenan, magnesium chloride, ascorbic acid, L-methionine, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

C. Isomil® SF Sucrose-Free Soy Formula With Iron.

Usage: As a beverage for infants, children and adults with an allergy or sensitivity to cow's-milk protein or an intolerance to sucrose. A feeding for patients with disorders for which lactose and sucrose should be avoided.

Features:

- Soy protein isolate to avoid symptoms of cow's-milk-protein allergy or sensitivity.

- Lactose-free formulation to avoid lactose-associated diarrhea (carbohydrate source is Polycose® Glucose Polymers).

- Sucrose free for the patient who cannot tolerate sucrose.

- Low osmolality (180 mOsm/kg water) to reduce risk of osmotic diarrhea.
- 1.8 mg of iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.
- Recommended levels of vitamins and minerals.
- Vegetable oils to provide recommended levels of essential fatty acids.
- Milk-white color, milk-like consistency and pleasant aroma.

Ingredients: (Pareve, ®) 75% water, 11.8% hydrolized cornstarch, 4.1% soy oil, 4.1% soy protein isolate, 2.8% coconut oil, 1.0% modified cornstarch, 0.38% calcium phosphate tribasic, 0.17% potassium citrate, 0.13% potassium chloride, mono- and disglycerides, soy lecithin, magnesium chloride, abscorbic acid, L-methionine, calcium carbonate, sodium chloride, choline chloride, carrageenan, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

D. Isomil® 20 Soy Formula With Iron Ready To Feed, 20 Cal/fl oz.

Usage: When a soy feeding is desired.

Ingredients: (Pareve, ®) 85% water, 4.9% corn syrup, 2.6% sugar (sucrose), 2.1% soy oil, 1.9% soy protein isolate, 1.4% coconut oil, 0.15% calcium citrate, 0.11% calcium phosphate tribasic, potassium citrate, potassium phosphate monobasic, potassium chloride, mono- and disglycerides, soy lecithin, carrageenan, abscorbic acid, L-methionine, magnesium chloride, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic

acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

E. Similac® Infant Formula

Usage: When an infant formula is needed: if the decision is made to discontinue breastfeeding before age 1 year, if a supplement to breastfeeding is needed or as a routine feeding if breastfeeding is not adopted.

Features:

- Protein of appropriate quality and quantity for good growth; heat-denatured, which reduces the risk of milk-associated enteric blood loss.
- Fat from a blend of vegetable oils (doubly homogenized), providing essential linoleic acid that is easily absorbed.
- Carbohydrate as lactose in proportion similar to that of human milk.
- Low renal solute load to minimize stress on developing organs.
- Powder, Concentrated Liquid and Ready To Feed forms.

Ingredients: (®-D) Water, nonfat milk, lactose, soy oil, coconut oil, mono- and diglycerides, soy lecithin, abscorbic acid, carrageenan, choline chloride, taurine, m-inositol, alpha-tocopheryl acetate, zinc sulfate, niacinamid, ferrous sulfate, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

F. Similac® NeoCare Premature Infant Formula With Iron

Usage: For premature infants' special nutritional needs after hospital discharge. Similac NeoCare is a nutritionally complete formula developed to provide premature infants with extra calories, protein, vitamins and minerals needed to promote catch-up growth and support development.

Features:

- Reduces the need for caloric and vitamin supplementation. More calories (22 Cal/fl oz) then standard term formulas (20 Cal/fl oz).
- Highly absorbed fat blend, with medium-chain triglycerides (MCT oil) to help meet the special digestive needs of premature infants.
- Higher levels of protein, vitamins and minerals per 100 Calories to extend the nutritional support initiated in-hospital.
- More calcium and phosphorus for improved bone mineralization.

Ingredients: ®-D Corn syrup solids, nonfat milk, lactose, whey protein concentrate, soy oil, high-oleic safflower oil, fractionated coconut oil (medium-chain triglycerides), coconut oil, potassium citrate, calcium phosphate tribasic, calcium carbonate, ascorbic acid, magnesium chloride, potassium chloride, sodium chloride, taurine, ferrous sulfate, m-inositol, choline chloride, ascorbyl palmitate, L-carnitine, alpha-tocopheryl acetate, zinc sulfate, niacinamide, mixed tocopherols, sodium citrate, calcium pantothenate, cupric sulfate, thiamine chloride hydrochloride, vitamin A palmitate, beta carotene, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

G. Similac Natural Care Low-Iron Human Milk Fortifier Ready To Use, 24 Cal/fl oz.

Usage: Designed to be mixed with human milk or to be fed alternatively with human milk to low-birth-weight infants.

Ingredients: ®-D Water, nonfat milk, hydrolyzed cornstarch, lactose, fractionated coconut oil (medium-chain triglycerides), whey protein concentrate, soil oil, coconut oil, calcium phosphate tribasic, potassium citrate, magnesium chloride, sodium citrate, ascorbic acid, calcium carbonate, mono- and diglycerides, soy lecithin, carrageenan, choline chloride, m-inositol, taurine, niacinamide, L-carnitine, alpha tocopheryl acetate, zinc sulfate, potassium chloride, calcium pantothenate, ferrous sulfate, cupric sulfate, riboflavin, vitamin A palmitate, thiamine chloride hydrochloride, pyridoxine

hydrochloride, biotin, folic acid, manganese sulfate, phylloquinone, vitamin D_3, sodium selenite and cyanocobalamin.

Various PUFAs of this invention can be substituted and/or added to the infant formulae described above and to other infant formulae known to those in the art..

II. NUTRITIONAL FORMULATIONS

A. ENSURE®

Usage: ENSURE is a low-residue liquid food designed primarily as an oral nutritional supplement to be used with or between meals or, in appropriate amounts, as a meal replacement. ENSURE is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets. Although it is primarily an oral supplement, it can be fed by tube.

Patient Conditions:

- For patients on modified diets
- For elderly patients at nutrition risk
- For patients with involuntary weight loss
- For patients recovering from illness or surgery
- For patients who need a low-residue diet

Ingredients:

®-D Water, Sugar (Sucrose), Maltodextrin (Corn), Calcium and Sodium Caseinates, High-Oleic Safflower Oil, Soy Protein Isolate, Soy Oil, Canola Oil, Potassium Citrate, Calcium Phosphate Tribasic, Sodium Citrate, Magnesium Chloride, Magnesium Phosphate Dibasic, Artificial Flavor, Sodium Chloride, Soy Lecithin, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Gellan Gum, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Folic Acid, Sodium Molybdate, Chromium Chloride, Biotin, Potassium Iodide, Sodium Selenate.

B. ENSURE® BARS

Usage: ENSURE BARS are complete, balanced nutrition for supplemental use between or with meals. They provide a delicious, nutrient-rich alternative to other snacks. ENSURE BARS contain <1 g lactose/bar, and Chocolate Fudge Brownie flavor is gluten-free. (Honey Graham Crunch flavor contains gluten.)

Patient Conditions:

- For patients who need extra calories, protein, vitamins and minerals
- Especially useful for people who do not take in enough calories and nutrients
- For people who have the ability to chew and swallow
- Not to be used by anyone with a peanut allergy or any type of allergy to nuts.

Ingredients:

Honey Graham Crunch -- High-Fructose Corn Syrup, Soy Protein Isolate, Brown Sugar, Honey, Maltodextrin (Corn), Crisp Rice (Milled Rice, Sugar [Sucrose], Salt [Sodium Chloride] and Malt), Oat Bran, Partially Hydrogenated Cottonseed and Soy Oils, Soy Polysaccharide, Glycerine, Whey Protein Concentrate, Polydextrose, Fructose, Calcium Caseinate, Cocoa Powder, Artificial Flafors, Canola Oil, High-Oleic Safflower Oil, Nonfat Dry Milk, Whey Powder, Soy Lecithin and Corn Oil. Manufactured in a facility that processes nuts.

Vitamins and Minerals:

Calcium Phosphate Tribasic, Potassium Phosphate Dibasic, Magnesium Oxide, Salt (Sodium Chloride), Potassium Chloride, Ascorbic Acid, Ferric Orthophosphate, Alpha-Tocopheryl Acetate, Niacinamide, Zinc Oxide, Calcium Pantothenate, Copper Gluconate, Manganese Sulfate, Riboflavin, Beta-Carotene, Pyridoxine Hydrochloride, Thiamine Mononitrate, Folic Acid, Biotin,

Chromium Chloride, Potassium Iodide, Sodium Selenate, Sodium Molybdate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein:

Honey Graham Crunch - The protein source is a blend of soy protein isolate and milk proteins.

Soy protein isolate	74%
Milk proteins	26%

Fat:

Honey Graham Crunch - The fat source is a blend of partially hydrogenated cottonseed and soybean, canola, high oleic safflower, and corn oils, and soy lecithin.

Partially hydrogenated cottonseed and soybean oil	76%
Canola oil	8%
High-oleic safflower oil	8%
Corn oil	4%
Soy lecithin	4%

Carbohydrate:

Honey Graham Crunch - The carbohydrate source is a combination of high-fructose corn syrup, brown sugar, maltodextrin, honey, crisp rice, glycerine, soy polysaccharide, and oat bran.

High-fructose corn syrup	24%
Brown sugar	21%
Maltodextrin	12%
Honey	11%
Crisp rice	9%
Glycerine	9%
Soy polysaccharide	7%
Oat bran	7%\

C. ENSURE® HIGH PROTEIN

Usage: ENSURE HIGH PROTEIN is a concentrated, high-protein liquid food designed for people who require additional calories, protein, vitamins, and minerals in their diets. It can be used as an oral nutritional supplement with or between meals or, in appropriate amounts, as a meal replacement. ENSURE HIGH PROTEIN is lactose- and gluten-free, and is suitable for use by people recovering from general surgery or hip fractures and by patients at risk for pressure ulcers.

Patient Conditions

- For patients who require additional calories, protein, vitamins, and minerals, such as patients recovering from general surgery or hip fractures, patients at risk for pressure ulcers, and patients on low-cholesterol diets

Features-

- Low in saturated fat
- Contains 6 g of total fat and < 5 mg of cholesterol per serving
- Rich, creamy taste
- Excellent source of protein, calcium, and other essential vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients:

Vanilla Supreme: -®-D Water, Sugar (Sucrose), Maltodextrin (Corn), Calcium and Sodium Caseinates, High-Oleic Safflower Oil, Soy Protein Isolate, Soy Oil, Canola Oil, Potassium Citrate, Calcium Phosphate Tribasic, Sodium Citrate, Magnesium Chloride, Magnesium Phosphate Dibasic, Artificial Flavor, Sodium Chloride, Soy Lecithin, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Suffate, Alpha-Tocopheryl Acetate, Gellan Gum, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride,

Riboflavin, Folio Acid, Sodium Motybdate, Chromium Chloride, Biotin, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D.3 and Cyanocobalarnin.

Protein:

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	85%
Soy protein isolate	15%

Fat:

The fat source is a blend of three oils: high-oleic safflower, canola, and soy.

High-oleic safflower oil	40%
Canola oil	30%
Soy oil	30%

The level of fat in ENSURE HIGH PROTEIN meets American Heart Association (AHA) guidelines. The 6 grams of fat in ENSURE HIGH PROTEIN represent 24% of the total calories, with 2.6% of the fat being from saturated fatty acids and 7.9% from polyunsaturated fatty acids. These values are within the AHA guidelines of $\leq$ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and $\leq$ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate:

ENSURE HIGH PROTEIN contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla supreme, chocolate royal, wild berry, and banana), plus VARI-FLAVORSO® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Sucrose	60%

Maltodextrin	40%
Chocolate	
Sucrose	70%
Maltodextrin	30%

D. ENSURE ® LIGHT

Usage: ENSURE LIGHT is a low-fat liquid food designed for use as an oral nutritional supplement with or between meals. ENSURE LIGHT is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions:

- For normal-weight or overweight patients who need extra nutrition in a supplement that contains 50% less fat and 20% fewer calories than ENSURE
- For healthy adults who don't eat right and need extra nutrition

Features:

- Low in fat and saturated fat
- Contains 3 g of total fat per serving and < 5 mg cholesterol
- Rich, creamy taste
- Excellent source of calcium and other essential vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients:

French Vanilla: ®-D Water, Maltodextrin (Corn), Sugar (Sucrose), Calcium Caseinate, High-Oleic Safflower Oil, Canola Oil, Magnesium Chloride, Sodium Citrate, Potassium Citrate, Potassium Phosphate Dibasic, Magnesium Phosphate Dibasic, Natural and Artificial Flavor, Calcium Phosphate Tribasic, Cellulose Gel, Choline Chloride, Soy Lecithin, Carrageenan, Salt (Sodium Chloride),

Ascorbic Acid, Cellulose Gum, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Zinc Sulfate, Niacinamide, Manganese Sulfate, Calcium Pantothenate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Vitamin A Palmitate, Pyridoxine Hydrochloride, Riboflavin, Chromium Chloride, Folic Acid, Sodium Molybdate, Biotin, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein:

The protein source is calcium caseinate.

Calcium caseinate	100%

Fat

The fat source is a blend of two oils: high-oleic safflower and canola.

High-oleic safflower oil	70%
Canola oil	30%

The level of fat in ENSURE LIGHT meets American Heart Association (AHA) guidelines. The 3 grams of fat in ENSURE LIGHT represent 13.5% of the total calories, with 1.4% of the fat being from saturated fatty acids and 2.6% from polyunsaturated fatty acids. These values are within the AHA guidelines of $\leq$ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and $\leq$ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate

ENSURE LIGHT contains a combination of maltodextrin and sucrose. The chocolate flavor contains corn syrup as well. The mild sweetness and flavor variety (French vanilla, chocolate supreme, strawberry swirl), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Sucrose	51%
Maltodextrin	49%

Chocolate

Sucrose	47.0%
Corn Syrup	26.5%
Maltodextrin	26.5%

Vitamins and Minerals

An 8-fl-oz serving of ENSURE LIGHT provides at least 25% of the RDIs for 24 key vitamins and minerals.

Caffeine

Chocolate flavor contains 2.1 mg caffeine/8 fl oz.

E. ENSURE PLUS®

Usage: ENSURE PLUS is a high-calorie, low-residue liquid food for use when extra calories and nutrients, but a normal concentration of protein, are needed. It is designed primarily as an oral nutritional supplement to be used with or between meals or, in appropriate amounts, as a meal replacement. ENSURE PLUS is lactose- and gluten-free. Although it is primarily an oral nutritional supplement, it can be fed by tube.

Patient Conditions:

- For patients who require extra calories and nutrients, but a normal concentration of protein, in a limited volume
- For patients who need to gain or maintain healthy weight

Features

- Rich, creamy taste
- Good source of essential vitamins and minerals

Ingredients

Vanilla: ®-D Water, Corn Syrup, Maltodextrin (Corn), Corn Oil, Sodium and Calcium Caseinates, Sugar (Sucrose), Soy Protein Isolate, Magnesium Chloride,

Potassium Citrate, Calcium Phosphate Tribasic, Soy Lecithin, Natural and Artificial Flavor, Sodium Citrate, Potassium Chloride, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Chromium Chloride, Sodium Molybdate, Potassium Iodide, Sodium Selenite, Phylloquinone, Cyanocobalamin and Vitamin D_3.

Protein

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	84%
Soy protein isolate	16%

Fat

The fat source is corn oil.

Corn oil	100%

Carbohydrate

ENSURE PLUS contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla, chocolate, strawberry. coffee, buffer pecan, and eggnog), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry. lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla, strawberry, butter pecan, and coffee flavors

Corn Syrup	39%
Maltodextrin	38%
Sucrose	23%

Chocolate and eggnog flavors

Corn Syrup	36%

Maltodextrin	34%
Sucrose	30%

Vitamins and Minerals

An 8-fl-oz serving of ENSURE PLUS provides at least 15% of the RDIs for 25 key Vitamins and minerals.

Caffeine

Chocolate flavor contains 3.1 mg Caffeine/8 fl oz. Coffee flavor contains a trace amount of caffeine.

F. ENSURE PLUS® HN

Usage: ENSURE PLUS HN is a nutritionally complete high-calorie, high-nitrogen liquid food designed for people with higher calorie and protein needs or limited volume tolerance. It may be used for oral supplementation or for total nutritional support by tube. ENSURE PLUS HN is lactose- and gluten-free.

Patient Conditions:

- For patients with increased calorie and protein needs, such as following surgery or injury
- For patients with limited volume tolerance and early satiety

Features

- For supplemental or total nutrition
- For oral or tube feeding
- 1.5 CaVmL
- High nitrogen
- Calorically dense

Ingredients

Vanilla: ®-D Water, Maltodextrin (Corn), Sodium and Calcium Caseinates, Corn Oil, Sugar (Sucrose), Soy Protein Isolate, Magnesium Chloride, Potassium Citrate, Calcium Phosphate Tribasic, Soy Lecithin, Natural and Artificial Flavor, Sodium Citrate, Choline Chloride, Ascorbic Acid, Taurine, L-Carnitine, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Carrageenan, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Chromium Chloride, Sodium Molybdate, Potassium Iodide, Sodium Selenite, Phylloquinone, Cyanocobalamin and Vitamin D_3.

G. ENSURE® POWDER

Usage: ENSURE POWDER (reconstituted with water) is a low-residue liquid food designed primarily as an oral nutritional supplement to be used with or between meals. ENSURE POWDER is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions:

- For patients on modified diets
- For elderly patients at nutrition risk
- For patients recovering from illness/surgery
- For patients who need a low-residue diet

Features

- Convenient, easy to mix
- Low in saturated fat
- Contains 9 g of total fat and < 5 mg of cholesterol per serving
- High in vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients: ®-D Corn Syrup, Maltodextrin (Corn), Sugar (Sucrose), Corn Oil, Sodium and Calcium Caseinates, Soy Protein Isolate, Artificial Flavor, Potassium Citrate, Magnesium Chloride, Sodium Citrate, Calcium Phosphate Tribasic, Potassium Chloride, Soy Lecithin, Ascorbic Acid, Choline Chloride, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Thiamine Chloride Hydrochloride, Cupric Sulfate, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Sodium Molybdate, Chromium Chloride, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	84%
Soy protein isolate	16%

Fat

The fat source is corn oil.

Corn oil	100%

Carbohydrate

ENSURE POWDER contains a combination of corn syrup, maltodextrin, and sucrose. The mild sweetness of ENSURE POWDER, plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, helps to prevent flavor fatigue and aid in patient compliance.

Vanilla

Corn Syrup	35%
Maltodextrin	35%
Sucrose	30%

H. ENSURE® PUDDING

Usage: ENSURE PUDDING is a nutrient-dense supplement providing balanced nutrition in a nonliquid form to be used with or between meals. It is appropriate for consistency-modified diets (e.g., soft, pureed, or full liquid) or for people with swallowing impairments. ENSURE PUDDING is gluten-free.

Patient Conditions:

- For patients on consistency-modified diets (e.g., soft, pureed, or full liquid)
- For patients with swallowing impairments

Features

- Rich and creamy, good taste
- Good source of essential vitamins and minerals Convenient-needs no refrigeration
- Gluten-free

Nutrient Profile per 5 oz: Calories 250, Protein 10.9%, Total Fat 34.9%, Carbohydrate 54.2%

Ingredients:

Vanilla: ®-D Nonfat Milk, Water, Sugar (Sucrose), Partially Hydrogenated Soybean Oil, Modified Food Starch, Magnesium Sulfate. Sodium Stearoyl Lactylate, Sodium Phosphate Dibasic, Artificial Flavor, Ascorbic Acid, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Choline Chloride, Niacinamide, Manganese Sulfate, Calcium Pantothenate, FD&C Yellow #5, Potassium Citrate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, FD&C Yellow #6, Folic Acid, Biotin, Phylloquinone, Vitamin D3 and Cyanocobalamin.

Protein

The protein source is nonfat milk.

Nonfat milk	100%

Fat

The fat source is hydrogenated soybean oil.

Hydrogenated soybean oil	100%

Carbohydrate

ENSURE PUDDING contains a combination of sucrose and modified food starch. The mild sweetness and flavor variety (vanilla, chocolate, butterscotch, and tapioca) help prevent flavor fatigue. The product contains 9.2 grams of lactose per serving.

Vanilla and other nonchocolate flavors

Sucrose	56%
Lactose	27%
Modified food starch	17%

Chocolate

Sucrose	58%
Lactose	26%
Modified food starch	16%

I. ENSURE® WITH FIBER

Usage: ENSURE WITH FIBER is a fiber-containing, nutritionally complete liquid food designed for people who can benefit from increased dietary fiber and nutrients. ENSURE WITH FIBER is suitable for people who do not require a low-residue diet. It can be fed orally or by tube, and can be used as a nutritional supplement to a regular diet or, in appropriate amounts, as a meal replacement. ENSURE WITH FIBER is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions

- For patients who can benefit from increased dietary fiber and nutrients

Features

- New advanced formula-low in saturated fat, higher in vitamins and minerals
- Contains 6 g of total fat and < 5 mg of cholesterol per serving
- Rich, creamy taste
- Good source of fiber
- Excellent source of essential vitamins and minerals
- For low-cholesterol diets
- Lactose- and gluten-free

Ingredients

Vanilla: ®-D Water, Maltodextrin (Corn), Sugar (Sucrose), Sodium and Calcium Caseinates, Oat Fiber, High-Oleic Safflower Oil, Canola Oil, Soy Protein Isolate, Corn Oil, Soy Fiber, Calcium Phosphate Tribasic, Magnesium Chloride, Potassium Citrate, Cellulose Gel, Soy Lecithin, Potassium Phosphate Dibasic, Sodium Citrate, Natural and Artificial Flavors, Choline Chloride, Magnesium Phosphate, Ascorbic Acid, Cellulose Gum, Potassium Chloride, Carrageenan, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Zinc Sulfate, Niacinamide, Manganese Sulfate, Calcium Pantothenate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Folic Acid, Chromium Chloride, Biotin, Sodium Molybdate, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein

The protein source is a blend of two high-biologic-value proteins- casein and soy.

Sodium and calcium caseinates	80%
Soy protein isolate	20%

Fat

The fat source is a blend of three oils: high-oleic safflower, canola, and corn.

High-oleic safflower oil	40%
Canola oil	40%
Corn oil	20%

The level of fat in ENSURE WITH FIBER meets American Heart Association (AHA) guidelines. The 6 grams of fat in ENSURE WITH FIBER represent 22% of the total calories, with 2.01 % of the fat being from saturated fatty acids and 6.7% from polyunsaturated fatty acids. These values are within the AHA guidelines of ≤ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and ≤ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate

ENSURE WITH FIBER contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla, chocolate, and butter pecan), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Maltodextrin	66%
Sucrose	25%
Oat Fiber	7%
Soy Fiber	2%

Chocolate

Maltodextrin	55%
Sucrose	36%
Oat Fiber	7%

Soy Fiber 2%

Fiber

The fiber blend used in ENSURE WITH FIBER consists of oat fiber and soy polysaccharide. This blend results in approximately 4 grams of total dietary fiber per 8-fl-oz can. The ratio of insoluble to soluble fiber is 95:5.

The various nutritional supplements described above and known to others of skill in the art can be substituted and/or supplemented with the PUFAs of this invention.

J. Oxepa™ Nutritional Product

Oxepa is low-carbohydrate, calorically dense enteral nutritional product designed for the dietary management of patients with or at risk for ARDS. It has a unique combination of ingredients, including a patented oil blend containing eicosapentaenoic acid (EPA from fish oil), γ-linolenic acid (GLA from borage oil), and elevated antioxidant levels.

Caloric Distribution:

- Caloric density is high at 1.5 Cal/mL (355 Cal/8 fl oz), to minimize the volume required to meet energy needs.
- The distribution of Calories in Oxepa is shown in Table 7.

Table 7. Caloric Distribution of Oxepa

	per 8 fl oz.	per liter	% of Cal
Calories	355	1,500	---
Fat (g)	22.2	93.7	55.2
Carbohydrate (g)	25	105.5	28.1
Protein (g)	14.8	62.5	16.7
Water (g)	186	785	---

Fat:

- Oxepa contains 22.2 g of fat per 8-fl oz serving (93.7 g/L).
- The fat source is a oil blend of 31.8% canola oil, 25% medium-chain triglycerides (MCTs), 20% borage oil, 20% fish oil, and 3.2 % soy lecithin. The typical fatty acid profile of Oxepa is shown in Table 8.

- Oxepa provides a balanced amount of polyunsaturated, monounsaturated, and saturated fatty acids, as shown in Table 10.
- Medium-chain trigylcerides (MCTs) -- 25% of the fat blend -- aid gastric emptying because they are absorbed by the intestinal tract without emulsification by bile acids.

The various fatty acid components of Oxepa™ nutritional product can be substituted and/or supplemented with the PUFAs of this invention.

Table 8. Typical Fatty Acid Profile

	% Total Fatty Acids	g/8 fl oz*	g/L*
Caproic (6:0)	0.2	0.04	0.18
Caprylic (8:0)	14.69	3.1	13.07
Capric (10:0)	11.06	2.33	9.87
Palmitic (16:0)	5.59	1.18	4.98
Palmitoleic (16:1n-7)	1.82	0.38	1.62
Stearic (18:0)	1.84	0.39	1.64
Oleic (18:1n-9)	24.44	5.16	21.75
Linoleic (18:2n-6)	16.28	3.44	14.49
α-Linolenic (18:3n-3)	3.47	0.73	3.09
γ-Linolenic (18:3n-6)	4.82	1.02	4.29
Eicosapentaenoic (20:5n-3)	5.11	1.08	4.55
n-3-Docosapentaenoic (22:5n-3)	0.55	0.12	0.49
Docosahexaenoic (22:6n-3)	2.27	0.48	2.02
Others	7.55	1.52	6.72

* Fatty acids equal approximately 95% of total fat.

Table 9. Fat Profile of Oxepa.

% of total calories from fat	55.2
Polyunsaturated fatty acids	31.44 g/L
Monounsaturated fatty acids	25.53 g/L
Saturated fatty acids	32.38 g/L
n-6 to n-3 ratio	1.75:1
Cholesterol	9.49 mg/8 fl oz 40.1 mg/L

Carbohydrate:

- The carbohydrate content is 25.0 g per 8-fl-oz serving (105.5 g/L).

- The carbohydrate sources are 45% maltodextrin (a complex carbohydrate) and 55% sucrose (a simple sugar), both of which are readily digested and absorbed.

- The high-fat and low-carbohydrate content of Oxepa is designed to minimize carbon dioxide (CO_2) production. High CO_2 levels can complicate weaning in ventilator-dependent patients. The low level of carbohydrate also may be useful for those patients who have developed stress-induced hyperglycemia.

- Oxepa is lactose-free.

Dietary carbohydrate, the amino acids from protein, and the glycerol moiety of fats can be converted to glucose within the body. Throughout this process, the carbohydrate requirements of glucose-dependent tissues (such as the central nervous system and red blood cells) are met. However, a diet free of carbohydrates can lead to ketosis, excessive catabolism of tissue protein, and loss of fluid and electrolytes. These effects can be prevented by daily ingestion of 50 to 100 g of digestible carbohydrate, if caloric intake is adequate. The carbohydrate level in Oxepa is also sufficient to minimize gluconeogenesis, if energy needs are being met.

Protein:

- Oxepa contains 14.8 g of protein per 8-fl-oz serving (62.5 g/L).

- The total calorie/nitrogen ratio (150:1) meets the need of stressed patients.

- Oxepa provides enough protein to promote anabolism and the maintenance of lean body mass without precipitating respiratory problems. High protein intakes are a concern in patients with respiratory insufficiency. Although protein has little effect on CO_2 production, a high protein diet will increase ventilatory drive.

- The protein sources of Oxepa are 86.8% sodium caseinate and 13.2% calcium caseinate.
- As demonstrated in Table 11, the amino acid profile of the protein system in Oxepa meets or surpasses the standard for high quality protein set by theNational Academy of Sciences.
- Oxepa is gluten-free.

All publications and patent applications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference.

The invention now being fully described, it will be apparent to one of ordinary skill in the art that many changes and modifications can be made thereto without departing from the spirit or scope of the appended claims.

What is claimed is:

1. An isolated nucleic acid comprising:

a nucleotide sequence depicted in SEQ ID NO: 1 or SEQ ID NO: 3.

2. A polypeptide encoded by a nucleotide sequence according to claim 1.

3. A purified or isolated polypeptide comprising an amino acid sequence depicted in SEQ ID NO: 2 or SEQ ID NO: 4.

4. An isolated nucleic acid encoding a polypeptide having an amino acid sequence depicted in SEQ ID NO: 2 or SEQ ID NO: 4.

5. An isolated nucleic acid comprising a nucleotide sequence which encodes a polypeptide which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end of said polypeptide, wherein said nucleotide sequence has an average A/T content of less than about 60%.

6. The isolated nucleic acid according to Claim 5, wherein said nucleic acid is derived from a fungus.

7. The isolated nucleic acid according to Claim 6, wherein said fungus is of the genus *Mortierella*.

8. The isolated nucleic acid according to Claim 7, wherein said fungus is of the species *Mortierella alpina*.

9. An isolated nucleic acid, wherein the nucleotide sequence of said nucleic acid is depicted in SEQ ID NO: 1. or SEQ ID NO: 3.

10. An isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end of said polypeptide, wherein said polypeptide is a eukaryotic polypeptide or is derived from a eukaryotic polypeptide.

11. The isolated or purified eukaryotic polypeptide according to Claim 10, wherein said eukaryotic polypeptide is derived from a fungus.

12. A nucleic acid comprising:

a fungal nucleotide sequence which is substantially identical to a sequence of at least 50 nucleotides in SEQ ID NO: 1 or SEQ ID NO: 3 or is complementary to a sequence of at least 50 nucleotides in SEQ ID NO: 1 or SEQ ID NO: 3.

13. An isolated nucleic acid having a nucleotide sequence with at least about 50% homology to SEQ ID NO: 1 or SEQ ID NO: 3.

14. An isolated nucleic acid having a nucleotide sequence with at least about 50% homology to sequence encoding an amino acid sequence depicted in SEQ ID NO: 2 or SEQ ID NO: 4.

15. The nucleic acid of claim 14, wherein said amino acid sequence depicted in SEQ ID NO: 2 is selected from the group consisting of amino acid residues 50-53, 39-43, 172-176, 204-213, and 390-402.

16. A nucleic acid construct comprising:

a nucleotide sequence depicted in a SEQ ID NO: 1 or SEQ ID NO: 3 linked to a heterologous nucleic acid.

17. A nucleic acid construct comprising:

a nucleotide sequence depicted in a SEQ ID NO: 1 or SEQ ID NO: 3 operably associated with an expression control sequence functional in a microbial cell.

18. The nucleic acid construct according to Claim 17, wherein said microbial cell is a yeast cell.

19. The nucleic acid construct according to Claim 17, wherein said nucleotide sequence is derived from a fungus.

20. The nucleic acid construct according to Claim 19, wherein said fungus is of the genus *Mortierella*.

21. The nucleic acid construct according to Claim 20, wherein said fungus is of the species *Mortierella alpina*.

22. A nucleic acid construct comprising:

a fungal nucleotide sequence which encodes a polypeptide comprising an amino acid sequence which corresponds to or is complementary to an amino acid sequence depicted in SEQ ID NO: 2 or SEQ ID NO: 4, wherein said nucleic acid is operably associated with an expression control sequence functional in a microbial cell, wherein said nucleotide sequence encodes a functionally active polypeptide which desaturates a fatty acid molecule at carbon 6 or 12 from the carboxyl end of a fatty acid molecule.

23. A nucleic acid construct comprising:

a nucleotide sequence having an A/T content of less than about 60% which encodes a functionally active Δ6-desaturase having an amino acid sequence which corresponds to or is complementary to all of or a portion of an amino acid sequence depicted in a SEQ ID NO: 2, wherein said nucleotide sequence is operably associated with a transcription control sequence functional in a yeast cell.

24. A nucleic acid construct comprising:

a fungal nucleotide sequence which encodes a functionally active Δ12-desaturase having an amino acid sequence which corresponds to or is complementary to all of or a portion of an amino acid sequence depicted in a SEQ ID NO: 4, wherein said nucleotide sequence is operably associated with a transcription control sequence functional in a yeast cell.

25. A recombinant yeast cell comprising:

a nucleic acid construct according to Claim 23 or Claim 24.

26. The recombinant yeast cell according to Claim 25, wherein said yeast cell is a *Saccharomyces* cell.

27. A recombinant yeast cell comprising:

at least one copy of a vector comprising a fungal nucleotide sequence which encodes a polypeptide which converts 18:2 fatty acids to 18:3 fatty acids or 18:3 fatty acids to 18:4 fatty acids, wherein said yeast cell or an ancestor of said yeast cell was transformed with said vector to produce said recombinant yeast cell, and wherein said nucleotide sequence is operably associated with an expression control sequence functional in said recombinant yeast cell.

28. The recombinant yeast cell according to claim 27, wherein said fungal nucleotide sequence is a *Mortierella* nucleotide sequence.

29. The recombinant yeast cell according to Claim 28, wherein said recombinant yeast cell is a *Saccharomyces* cell.

30. The microbial cell according to Claim 27, wherein said expression control sequence is provided in said expression vector.

31. A method for production of GLA in a yeast culture, said method comprising:

growing a yeast culture having a plurality of recombinant yeast cells, wherein said yeast cells or an ancestor of said yeast cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts LA to GLA, wherein said DNA is operably associated with an expression control sequence functional in said yeast cells, under conditions whereby said DNA is expressed, whereby GLA is produced from LA in said yeast culture.

32. The method according to Claim 31, wherein said fungal DNA is *Mortierella* DNA and said polypeptide is a Δ6 desaturase.

33. The method according to Claim 32, wherein *Mortierella* is of the species *Mortierella alpina*.

34. The method according to Claim 31, wherein said LA is exogenously supplied.

35. The method according to Claim 31, wherein said conditions are inducible.

36. A method for production of stearidonic acid in a yeast culture, said method comprising:

growing a yeast culture having a plurality of recombinant yeast cells, wherein said yeast cells or an ancestor of said yeast cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts α-linolenic acid to stearidonic acid, wherein said DNA is operably associated with an expression control sequence functional in said yeast cells, under conditions whereby said DNA is expressed, whereby stearidonic acid is produced from α-linolenic acid in said yeast culture.

37. The method according to Claim 36, wherein said fungal DNA is *Mortierella* DNA and said polypeptide is a Δ6 desaturase.

38. The method according to Claim 37, wherein *Mortierella* is of the species *Mortierella alpina*.

39. The method according to Claim 36, wherein said α-linolenic acid is exogenously supplied.

40. The method according to Claim 36, wherein said conditions are inducible.

41. A method for production of linoleic acid in a yeast culture, said method comprising:

growing a yeast culture having a plurality of recombinant yeast cells, wherein said yeast cells or an ancestor of said yeast cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts oleic acid to linoleic acid, wherein said DNA is operably associated with an expression control sequence functional in said yeast cells, under conditions whereby said DNA is expressed, whereby linoleic acid is produced from oleic acid in said yeast culture.

42. The method according to Claim 41, wherein said fungal DNA is *Mortierella* DNA and said polypeptide is a Δ12 desaturase.

43. The method according to Claim 42, wherein *Mortierella* is of the species *Mortierella alpina*.

44. The method according to Claim 41, wherein said conditions are inducible.

45. An isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 12 from the carboxyl end of said polypeptide, wherein said polypeptide is a fungal polypeptide or is derived from a fungal polypeptide.

46. The isolated or purified polypeptide according to Claim 46, wherein said polypeptide is a *Mortierrella alpina* Δ12 desaturase.

47. An isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 6 from the carboxyl end of said polypeptide, wherein said polypeptide is a fungal polypeptide or is derived from a fungal polypeptide.

48. The isolated or purified polypeptide according to Claim 48, wherein said polypeptide is a Δ6 desaturase.

49. An isolated nucleic acid encoding a polypeptide according to Claim 47 or Claim 49.

50. The nucleic acid construct according to Claim 23, wherein said portion of an amino acid sequence depicted in SEQ.ID. NO: 2 comprises amino acids 1 through 457.

51. A host cell comprising:

a nucleic acid construct according to any one of Claims 22 to 24.

52. A host cell comprising:

a vector which includes a nucleic acid which encodes a fatty acid desaturase derived from *Mortierella alpina*, wherein said desaturase has an amino acid sequence represented by SEQ ID NO:2, and wherein said nucleotide sequence is operably linked to a promoter.

53. The host cell according to Claim 52, wherein said host cell is a eukaryotic cell.

54. The host cell according to Claim 53, wherein said eukaryotic cell is selected from the group consisting of a mammalian cell, a plant cell, an insect cell, a fungal cell, an avian cell and an algal cell.

55. The host cell according to Claim 54, wherein said host cell is a fungal cell.

56. The host cell of Claim 21, wherein said promoter is exogenously supplied to said host cell.

57. A method for production of stearidonic acid in a eukaryotic cell culture, said method comprising:

growing a eukaryotic cell culture having a plurality of recombinant eukaryotic cells, wherein said recombinant eukaryotic cells or ancestors of said recombinant eukaryotic cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts α-linolenic acid to stearidonic acid, wherein said DNA is operably associated with an expression control sequence functional in said recombinant eukaryotic cells, under conditions whereby said DNA is expressed, whereby stearidonic acid is produced from α-linolenic acid in said eukaryotic cell culture.

58. A method for production of linoleic acid in a eukaryotic cell culture, said method comprising:

growing a eukaryotic cell culture having a plurality of recombinant eukaruyotic cells, wherein said recombinant eukaryotic cells or ancestors of said recombinant eukaryotic cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts oleic acid to linoleic acid, wherein said DNA is operably associated with an expression control sequence functional in said recombinant eukaryotic cells, under conditions whereby said DNA is expressed, whereby linoleic acid is produced from oleic acid in said eukaryotic cell culture.

59. The method according to Claim 57 or Claim 58, wherein said eukaryotic cells are selected from the group consisting of mammalian cells, plant cells, insect cells, fungal cells, avian cells and algal cells.

60. The method according to Claim 59, wherein said fungal cells are yeast cells of the genus *Saccharomyces*.

61. A recombinant yeast cell comprising:

(1) at least one nucleic acid construct according to Claim 23 or 24; or

(2) at least one nucleic acid construct according to Claim 23 and at least one nucleic acid construct according to Claim 24.

62. A recombinant yeast cell comprising:

at least one nucleic acid construct comprising a nucleotide sequence which encodes a functionally active Δ6 desaturase having an amino acid sequence which corresponds to or is complementary to all or a portion of an amino acid sequence depicted in SEQ ID NO: 2, and at least one nucleic acid construct comprising a nucleotide sequence which encodes a functionally active Δ12 desaturase having an amino acid sequence which corresponds to or is complementary to all or a portion of an amino acid sequence depicted in SEQ ID NO: 4, wherein said nucleic acid constructs are operably associated with transcription control sequences functional in a yeast cell.

63. A method of making GLA, said method comprising:

growing a recombinant yeast cell according to Claim 62 under conditions whereby said nucleotide sequences are expressed , whereby GLA is produced in said yeast cell.

64. A method of making GLA, said method comprising:

growing a recombinant yeast cell according to Claim 61 under conditions whereby the nucleotide sequences in said nucleic acid constructs are expressed , whereby GLA is produced in said yeast cell.

65. A method for obtaining altered long chain polyunsaturated fatty acid biosynthesis comprising the steps of:

growing a plant having cells which contain one or more transgenes, derived from a fungus or algae, which encodes a transgene expression product which desaturates a fatty acid molecule at a carbon selected from the group consisting of carbon 6 and carbon 12 from the carboxyl end of said fatty acid molecule, wherein said one or more trangenes is operably associated with an expression control sequence, under conditions whereby said one or more transgenes is expressed, whereby long chain polyunsaturated fatty acid biosynthesis in said cells is altered.

66. The method according to claim 65, wherein said long chain polyunsaturated fatty acid is selected from the group consisting of 18:1ω9, LA, GLA, SDA and ALA.

67. A microbial oil or fraction thereof produced according to the method of claim 65.

68. A method of treating or preventing malnutrition comprising administering said microbial oil of claim 67 to a patient in need of said treatment or prevention in an amount sufficient to effect said treatment or prevention.

69. A pharmaceutical composition comprising said microbial oil or fraction of claim 67 and a pharmaceutically acceptable carrier.

70. The pharmaceutical composition of claim 69, wherein said pharmaceutical composition is in the form of a solid or a liquid.

71. The pharmaceutical composition of claim 70, wherein said pharmaceutical composition is in a capsule or tablet form.

72. The pharmaceutical composition of claim 69 further comprising at least one nutrient selected from the group consisting of a vitamin, a mineral, a carbohydrate, a sugar, an amino acid, a free fatty acid, a phospholipid, an antioxidant, and a phenolic compound.

73. A nutritional formula comprising said microbial oil or fraction thereof of claim 67.

74. The nutritional formula of claim 73, wherein said nutritional formula is selected from the group consisting of an infant formula, a dietary supplement, and a dietary substitute.

75. The nutritional formula of claim 74, wherein said infant formula, dietary supplement or dietary supplement is in the form of a liquid or a solid.

76. An infant formula comprising said microbial oil or fraction thereof of claim 67.

77. The infant formula of claim 76 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

78. The infant formula of claim 77 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

79. A dietary supplement comprising said microbial oil or fraction thereof of claim 67.

80. The dietary supplement of claim 79 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

81. The dietary supplement of claim 80 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

82. The dietary supplement of claim 79 or claim 81, wherein said dietary supplement is administered to a human or an animal.

83. A dietary substitute comprising said microbial oil or fraction thereof of claim 67.

84. The dietary substitute of claim 83 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

85. The dietary substitute of claim 84 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group c nsisting of calcium, magnesium,

zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

86. The dietary substitute of claim 83 or claim 85, wherein said dietary substitute is administered to a human or animal.

87. A method of treating a patient having a condition caused by insuffient intake or production of polyunsaturated fatty acids comprising administering to said patient said dietary substitute of claim 83 or said dietary supplement of claim 79 in an amount sufficient to effect said treatment.

88. The method of claim 87, wherein said dietary substitute or said dietary supplement is administered enterally or parenterally.

89. A cosmetic comprising said microbial oil or fraction thereof of claim 67.

90. The cosmetic of claim 88, wherein said cosmetic is applied topically.

91. The pharmaceutical composition of claim 69, wherein said pharmaceutical composition is administered to a human or an animal.

92. An animal feed comprising said microbial oil or fraction thereof of claim 67.

93. The method of claim 20 wherein said fungus is *Mortierella species*.

94. The method of claim 93 wherein said fungus is *Mortierella alpina*.

95. An isolated peptide sequence selected from the group consisting of SEQ ID NO:34 - SEQ ID NO:40.

96. An isolated peptide sequence selected from the group consisting of SEQ ID NO:20, SEQ ID NO:22, SEQ ID NO:25 and SEQ ID NO:26.

97. A method for production of gamma-linolenic acid in a eukaryotic cell culture, said method comprising:

growing a eukaryotic cell culture having a plurality of recombinant eukaryotic cells, wherein said recombinant eukaryotic cells or ancestors of said recombinant eukaryotic cells were transformed with a vector comprising fungal DNA encoding a polypeptide which converts linoleic acid to gamma-linolenic acid, wherein said DNA is operably associated with an expression control sequence functional in said recombinant eukaryotic cells, under conditions whereby said DNA is expressed, whereby gamma-linolenic acid is produced from linoleic acid in said eukaryotic cell culture.

98. The method according to Claim 97 wherein said eukaryotic cells are selected from the group consisting of mammalian cells, plant cells, insect cells, fungal cells, avian cells and algal cells.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 98/07126

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C12N15/53 C12N15/81 C12N9/02 C12N5/10 C12N1/19
C12P7/64 C11B1/00 A61K31/20 A23L1/30

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 C12N C12P C11B A61K A23L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	COVELLO P. ET AL.: "Functional expression of the extraplastidial Arabidopsis thaliana oleate desaturase gene (FAD2) in Saccharomyces cerevisiae" PLANT PHYSIOLOGY, vol. 111, no. 1, May 1996, pages 223-226, XP002075211 see the whole document ---	10
X	WO 94 11516 A (DU PONT ;LIGHTNER JONATHAN EDWARD (US); OKULEY JOHN JOSEPH (US)) 26 May 1994 cited in the application	10
A	see the whole document ---	1-9, 11-98

-/--

[X] Further documents are listed in the continuation of box C.

[X] Patent family members are listed in annex.

° Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier document but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

Box I Observations wher certain claims w re found unsearchable (Continuati n of it m 1 f first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [X] Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 68, 87, 88 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. [X] Claims Nos.: (not applicable)
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
see FURTHER INFORMATION sheet PCT/ISA/210

3. [ ] Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. [ ] As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. [X] As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. [ ] As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. [ ] No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

[ ] The additional search fees were accompanied by the applicant's protest.

[ ] No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This international Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-94, 97, 98

Isolated nucleic acids comprising SEQ ID NO: 1,3, as well as polypeptides comprising SEQ ID NO: 2,4, homologs and fragments thereof.
An isolated or purified eukaryotic polypeptide which desaturates a fatty acid molecule at carbon 6 or 12, especially of fungal origin, especially of Mortierella alpina.
Nucleic acid constructs and vectors comprising delta-6, or delta 12 desaturases according to SEQ ID NO: 1,3, derived from the fungus Mortierella alpina.
Recombinant cells comprising said constructs.
Methods for the production of GLA, stearidonic acid, linoleic acid, or gamma-linolenic acid in eukaryotic cell cultures, especially yeast cultures, employing DNA sequences or constructs coding for delta-6, or delta-12 desaturases of fungal origin, especially of Mortierella alpina.
Methods for obtaining altered long chain polyunsaturated fatty acid biosynthesis using plants comprising delta-6, or delta-12 desaturases, or combinations thereof, derived from fungi or algae.
Plant oils derived from said plants and their use for therapeutical, nutritional, and cosmetical purposes, as well as products derived therefrom.

2. Claim : 95

An isolated peptides sequence selected from the group of SEQ ID NO: 34-40.

3. Claim : 96

An isolated peptides sequence selected from the group consisting of SEQ ID NO: 20, 22, 25, 26

Claims No.: not applicable

In view of the extremely broad claims 5-8, the search was executed with due regard to the PCT Search guidelines (PCT/GL/2), C-III, paragraph 2.2, 2.3 read in conjuction with 3.7 and Rule 33.3 PCT, i.e. particular emphasis was put on the inventive concept, as illustrated by Mortierella alpina fatty acid desaturases comprising the nucleotide sequences in SEQ ID NO:1 and 3.

(54) Title: METHODS AND COMPOSITIONS FOR SYNTHESIS OF LONG CHAIN POLYUNSATURATED FATTY ACIDS

(57) Abstract

The present invention relates to a fatty acid Δ5-desaturase able to catalyze the conversion of dihomo-gamma-linolenic acid to arachidonic acid. Nucleic acid sequences encoding Δ5-desaturase, nucleic acid sequences which hybridize thereto, DNA constructs comprising a Δ5-desaturase gene, and recombinant host microorganism or animal expressing increased levels of a Δ5-desaturase are described. Methods for desaturating a fatty acid at the Δ5 position and for producing arachidonic acid by expressing increased levels of a Δ5-desaturase are disclosed. Fatty acids, and oils containing them, which have been desaturated by a Δ5-desaturase produced by recombinant host microorganisms or animals are provided. Pharmaceutical compositions, infant formulas or dietary supplements containing fatty acids which have been desaturated by a Δ5-desaturase produced by a recombinant host microorganism or animal also are described.

METHODS AND COMPOSITIONS FOR SYNTHESIS OF LONG CHAIN POLYUNSATURATED FATTY ACIDS

RELATED APPLICATION

This application is a continuation in part application of Serial Number 08/833,610 filed April 11, 1997.

INTRODUCTION

Field of the Invention

This invention relates to modulating levels of enzymes and/or enzyme components relating to production of long chain poly-unsaturated fatty acids (PUFAs) in a microorganism or animal.

Background

Two main families of polyunsaturated fatty acids (PUFAs) are the ω3 fatty acids, exemplified by eicosapentaenoic acid (EPA), and the ω6 fatty acids, exemplified by arachidonic acid (ARA). PUFAs are important components of the plasma membrane of the cell, where they may be found in such forms as phospholipids. PUFAs are necessary for proper development, particularly in the developing infant brain, and for tissue formation and repair. PUFAs also serve as precursors to other molecules of importance in human beings and animals, including the prostacyclins, eicosanoids, leukotrienes and prostaglandins.

Four major long chain PUFAs of importance include docosahexaenoic acid (DHA) and EPA, which are primarily found in different types of fish oil, gamma-linolenic acid (GLA), which is found in the seeds of a number of plants, including evening primrose (*Oenothera biennis*), borage (*Borago officinalis*) and black currants (*Ribes nigrum*), and stearidonic acid (SDA), which is found in marine oils and plant seeds. Both GLA and another important long chain PUFA, arachidonic acid (ARA), are found in filamentous fungi. ARA can be

purified from animal tissues including liver and adrenal gland. GLA, ARA, EPA and SDA are themselves, or are dietary precursors to, important long chain fatty acids involved in prostaglandin synthesis, in treatment of heart disease, and in development of brain tissue.

Polyunsaturated fatty acids have a number of pharmaceutical and medical applications including treatment of heart disease, cancer and arthritis.

For DHA, a number of sources exist for commercial production including a variety of marine organisms, oils obtained from cold water marine fish, and egg yolk fractions. For ARA, microorganisms including the genera *Mortierella, Entomophthora, Phytium* and *Porphyridium* can be used for commercial production. Commercial sources of SDA include the genera *Trichodesma and Echium*. Commercial sources of GLA include evening primrose, black currants and borage. However, there are several disadvantages associated with commercial production of PUFAs from natural sources. Natural sources of PUFAs, such as animals and plants, tend to have highly heterogeneous oil compositions. The oils obtained from these sources therefore can require extensive purification to separate out one or more desired PUFAs or to produce an oil which is enriched in one or more PUFA. Natural sources also are subject to uncontrollable fluctuations in availability. Fish stocks may undergo natural variation or may be depleted by overfishing. Fish oils have unpleasant tastes and odors, which may be impossible to economically separate from the desired product, and can render such products unacceptable as food supplements. Animal oils, and particularly fish oils, can accumulate environmental pollutants. Weather and disease can cause fluctuation in yields from both fish and plant sources. Cropland available for production of alternate oil-producing crops is subject to competition from the steady expansion of human populations and the associated increased need for food production on the remaining arable land. Crops which do produce PUFAs, such as borage, have not been adapted to commercial growth and may not perform well in monoculture. Growth of such crops is thus not economically competitive where more profitable and better established crops can be grown. Large scale

fermentation of organisms such as *Mortierella* is also expensive. Natural animal tissues contain low amounts of ARA and are difficult to process. Microorganisms such as *Porphyridium* and *Mortierella* are difficult to cultivate on a commercial scale.

Dietary supplements and pharmaceutical formulations containing PUFAs can retain the disadvantages of the PUFA source. Supplements such as fish oil capsules can contain low levels of the particular desired component and thus require large dosages. High dosages result in ingestion of high levels of undesired components, including contaminants. Unpleasant tastes and odors of the supplements can make such regimens undesirable, and may inhibit compliance by the patient. Care must be taken in providing fatty acid supplements, as overaddition may result in suppression of endogenous biosynthetic pathways and lead to competition with other necessary fatty acids in various lipid fractions *in vivo*, leading to undesirable results. For example, Eskimos having a diet high in ω3 fatty acids have an increased tendency to bleed (U.S. Pat. No. 4,874,603).

A number of enzymes are involved in PUFA biosynthesis. Linolenic acid (LA, 18:2 Δ9, 12) is produced from oleic acid (18:1 Δ^{9}) by a Δ12-desaturase. GLA (18:3 Δ6, 9, 12) is produced from linoleic acid (LA, 18:2 Δ9, 12) by a Δ6-desaturase. ARA (20:4 Δ5, 8, 11, 14) production from dihomo-gamma-linolenic acid (DGLA, 20:3 Δ8, 11, 14) is catalyzed by a Δ5-desaturase. However, animals cannot desaturate beyond the Δ9 position and therefore cannot convert oleic acid (18:1 Δ9) into linolenic acid (18:2 Δ912). Likewise, α-linoleic acid (ALA, 18:3 Δ9, 12, 15) cannot be synthesized by mammals. Other eukaryotes, including fungi and plants, have enzymes which desaturate at positions Δ12 and Δ15. The major poly-unsaturated fatty acids of animals therefore are either derived from diet and/or from desaturation and elongation of linoleic acid (18:2 Δ9, 12) or ∝-linolenic acid (18:3 Δ9, 12, 15). Therefore it is of interest to obtain genetic material involved in PUFA biosynthesis from species that naturally produce these fatty acids and to express the isolated

material in a microbial or animal system which can be manipulated to provide production of commercial quantities of one or more PUFAs. Thus there is a need for fatty acid desaturases, genes encoding them, and recombinant methods of producing them. A need further exists for oils containing higher relative proportions of and/or enriched in specific PUFAs. A need also exists for reliable economical methods of producing specific PUFAs.

Relevant Literature

Production of gamma-linolenic acid by a Δ6-desaturase is described in USPN 5,552,306. Production of 8, 11-eicosadienoic acid using *Mortierella alpina* is disclosed in USPN 5,376,541. Production of docosahexaenoic acid by dinoflagellates is described in USPN 5,407,957. Cloning of a Δ6-palmitoyl-acyl carrier protein desaturase is described in PCT publication WO 96/13591 and USPN 5,614,400. Cloning of a Δ6-desaturase from borage is described in PCT publication WO 96/21022. Cloning of Δ9-desaturases is described in the published patent applications PCT WO 91/13972, EP 0 550 162 A1, EP 0 561 569 A2, EP 0 644 263 A2, and EP 0 736 598 A1, and in USPN 5,057,419. Cloning of Δ12-desaturases from various organisms is described in PCT publication WO 94/11516 and USPN 5,443,974. Cloning of Δ15-desaturases from various organisms is described in PCT publication WO 93/11245. All publications and U.S. patents or applications referred to herein are hereby incorporated in their entirety by reference.

Summary of the Invention

Novel compositions and methods are provided for preparation of poly-unsaturated long chain fatty acids or PUFAs. The compositions include nucleic acids encoding a Δ5-desaturase and/or polypeptides having Δ5-desaturase activity, the polypeptides, and probes for isolating and detecting the same. The methods involve growing a host microorganism or animal which contains and expresses one or more transgenes encoding a Δ5-desaturase and/or a polypeptide having Δ5-desaturase activity. Expression of the desaturase

polypeptide provides for a relative increase in Δ5-desaturated PUFA, or metabolic progeny therefrom, as a result of altered concentrations of enzymes and substrates involved in PUFA biosynthesis. The invention finds use for example in the large scale production of PUFA containing oils which include, for example, ARA, EPA and/or DHA.

In a preferred embodiment, a nucleic acid sequence comprising a Δ5-desaturase depicted in Figure 3A-D (SEQ ID NO 1), a polypeptide encoded by the nucleic acid, and a purified or isolated polypeptide depicted in Figure 3A-D (SEQ ID NO: 2), and an isolated nucleic acid encoding the polypeptide of Figure 3A-D (SEQ ID NO: 2) are provided. Another embodiment of the invention is an isolated nucleic acid sequence which encodes a polypeptide, wherein said polypeptide desaturates a fatty acid molecule at carbon 5 from the carboxyl end of the molecule. The nucleic acid is preferably derived from a eukaryotic cell, such as a fungal cell, or a fungal cell of the genus *Mortierella*, or of the genus/species *Mortierella alpina*. Also preferred is an isolated nucleic acid comprising a sequence which anneals to a nucleotide sequence depicted in Figure 3A-3D (SEQ ID NO: 1), and a nucleic acid which encodes an amino acid sequence depicted in Figure 3A-D (SEQ ID NO: 2). In particular, the nucleic acid encodes an amino acid sequence depicted in Figure 3A-D (SEQ ID NO: 2) which is selected from the group consisting of amino acid residues 30-38, 41-44, 171-175, 203-212, and 387-394. In an additional embodiment, the invention provides an isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of the molecule. Also provided is an isolated nucleic acid sequence which hybridizes to a nucleotide sequence depicted in Figure 3A-D (SEQ ID NO 1), an isolated nucleic acid sequence having at least about 50% identity to Figure 3A-D (SEQ ID NO 1).

The present invention further includes a nucleic acid construct comprising a nucleotide sequence depicted in a Figure 3A-D (SEQ ID NO: 1) linked to a heterologous nucleic acid; a nucleic acid construct comprising a nucleotide sequence depicted in a Figure 3A-D (SEQ ID NO: 1) operably linked to a promoter; and a nucleic acid construct comprising a nucleotide sequence

depicted in a Figure 3A-D (SEQ ID NO: 1) operably linked to a promoter which is functional in a microbial cell. In a preferred embodiment, the microbial cell is a yeast cell, and the nucleotide sequence is derived from a fungus, such as a fungus of the genus *Mortierella*, particularly a fungus of the species *Mortierella alpina*.

In another embodiment of the invention, a nucleic acid construct is provided which comprises a nucleotide sequence which encodes a polypeptide comprising an amino acid sequence which corresponds to or is complementary to an amino acid sequence depicted in Figure 3A-D (SEQ ID NO: 2), wherein the nucleotide sequence is operably linked to a promoter which is functional in a host cell, and wherein the nucleotide sequence encodes a polypeptide which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of a fatty acid molecule. Additionally, provided by the invention is a nucleic acid construct comprising a nucleotide sequence which encodes a functionally active Δ5-desaturase, where the desaturase includes an amino acid sequence which corresponds to or is complementary to all of or a portion of an amino acid sequence depicted in a Figure 3A-D (SEQ ID NO: 2), wherein the nucleotide sequence is operably linked to a promoter functional in a host cell.

The invention also includes a host cell comprising a nucleic acid construct of the invention. In a preferred embodiment, a recombinant host cell is provided which comprises at least one copy of a DNA sequence which encodes a functionally active *Mortierella alpina* fatty acid desaturase having an amino acid sequence as depicted in Figure 3A-D (SEQ ID NO: 2), wherein the cell or an ancestor of the cell was transformed with a vector comprising said DNA sequence, and wherein the DNA sequence is operably linked to a promoter. The host cell is either eukaryotic or prokaryotic. Preferred eukaryotic host cells are those selected from the group consisting of a mammalian cell, an insect cell, a fungal cell, and an algae cell. Preferred mammalian cells include an avian cell, a fungal cell such as a yeast, and a marine algae cell. Preferred prokaryotic cells include those selected from the group consisting of a bacteria, a cyanobacteria, cells which contain a

bacteriophage, and/or a virus. The DNA sequence of the recombinant host cell preferably contains a promoter which is functional in the host cell.

The host cells of the invention which contain the DNA sequences of the invention are enriched for fatty acids, such as 20:3 fatty acids. In a preferred embodiment, the host cells are enriched for 20:4 fatty acids as compared to an untransformed host cell which is devoid of said DNA sequence, and/or enriched for 20:5 fatty acids compared to an untransformed host cell which is devoid of said DNA sequence. In yet another preferred embodiment, the invention provides a recombinant host cell which comprises a fatty acid selected from the group consisting of a dihomo-γ-linolenic acid, n-6 eicosatrienoic acid, 20:3n-6 acid and 20:3 (8,11,14) acid.

The present invention also includes method for production of arachidonic acid in a microbial cell culture, where the method comprises growing a microbial cell culture having a plurality of microbial cells which contain one or more nucleic acids encoding a polypeptide which converts dihomo-γ-linolenic acid to arachidonic acid, wherein the nucleic acid is operably linked to a promoter, under conditions whereby said one or more nucleic acids are expressed, whereby arachidonic acid is produced in the microbial cell culture. In several preferred embodiments of the invention, the polypeptide is an enzyme which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of the fatty acid molecule; the nucleic acid is derived from a *Mortierella sp.*; and the substrate for said polypeptide is exogenously supplied. The microbial cells used in the methods can be either eukaryotic cells or prokaryotic cells. The preferred eukaryotic cells are those selected from the group consisting of a mammalian cell, an insect cell, a fungal cell, and an algae cell. Preferred mammalian cells include an avian cell, a preferred fungal cell is a yeast, and the preferred algae cell is a marine algae cell. The preferred prokaryotic cells include those selected from the group consisting of a bacteria, a cyanobacteria, cells which contain a bacteriophage, and/or a virus. The nucleic acid sequence encoding the polypeptide of the microbial cell preferably contains a promoter which is functional in the host cell which

optionally is an inducible promoter for example by components of the culture broth. The preferred microbial cells used in the methods are yeast cells, such as *Saccharomyces* cells.

In another embodiment of the invention, a recombinant yeast cell is provided which converts greater than about 5% of 20:3 fatty acid substrate to a 20:4 fatty acid product.

Also provided is an oil comprising one or more PUFA. The amount of said one or more PUFAs is approximately 0.3-30% arachidonic acid (ARA), approximately 0.2-30% dihomo-γ-linolenic acid (DGLA), and approximately 0.2-30% γ-linolenic acid (GLA). A preferred oil of the invention is one in which the ratio of ARA:DGLA:GLA is approximately 1.0:19.0:30 to 6.0:1.0:0.2. Another preferred embodiment of the invention is a pharmaceutical composition comprising the oils in a pharmaceutically acceptable carrier. Further provided is a nutritional composition comprising the oils of the invention. The nutritional compositions of the invention preferably are administered to a mammalian host parenterally or internally. A preferred composition of the invention for internal consumption is an infant formula. In a preferred embodiment, the nutritional compositions of the invention are in a liquid form or a solid form.

The present invention also includes a method for desaturating a fatty acid, where the method comprises culturing a recombinant microbial cell of the invention under conditions suitable for expression of a polypeptide encoded by the nucleic acid, wherein the host cell further comprises a fatty acid substrate of the polypeptide. In a preferred embodiment, a fatty acid desaturated by the methods is provided, including an oil comprising the fatty acid.

The present invention is also directed to purified nucleotide and peptide sequences presented in SEQ ID NO:1-34. The present invention is further directed toward methods of using the sequences presented in SEQ ID NO:1-34 as probes to identify related sequences, as components of expression systems and as components of systems useful for producing transgenic oil.

The present invention is further directed to methods of obtaining altered long chain poly unsaturated fatty acid biosystems by growing transgenic microbes which encode transgene expression products which desaturate a fatty acid molecule at carbon 5 from the carboxyl end of the fatty acid molecule.

The present invention is further directed to formulas, dietary supplements or dietary supplements in the form of a liquid or a solid containing the long chain fatty acids of the invention. These formulas and supplements may be administered to a human or an animal.

The formulas and supplements of the invention may further comprise at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

The formulas of the present invention may further include at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

The present invention is further directed to a method of treating a patient having a condition caused by insuffient intake or production of polyunsaturated fatty acids comprising administering to the patient a dietary substitute of the invention in an amount sufficient to effect treatment of the patient.

The present invention is further directed to cosmetic and pharmaceutical compositions of the material of the invention.

The present invention is also directed to an isolated nucleotide sequence comprising a nucleuotide sequence selected from the group consisting of: SEQ ID NO:13; SEQ ID NO:15; SEQ ID NO:17; SEQ ID NO:19; SEQ ID NO:21; SEQ ID NO:22; SEQ ID NO:22; SEQ ID NO:24; SEQ ID NO:25; SEQ ID NO:26 and SEQ ID NO:27.

The present invention is also directed to an isolated peptide sequence comprising a peptide sequence selected from the group consisting of: SEQ ID NO:14; SEQ ID NO:16; SEQ ID NO:18; SEQ ID NO:20; SEQ ID NO:28; SEQ ID NO:29; SEQ ID NO:30; SEQ ID NO:31; SEQ ID NO:32; SEQ ID NO:33 and SEQ ID NO:34.

The present invention is further directed to transgenic oils in pharmaceutically acceptable carriers. The present invention is further directed to nutritional supplements, cosmetic agents and infant formulae containing transgenic oils.

The present invention is further directed to a method for obtaining altered long chain polyunsaturated fatty acid biosynthesis comprising the steps of: growing a microbe having cells which contain a transgene which encodes a transgene expression product which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule, wherein the trangene is operably associated with an expression control sequence, under conditions whereby the transgene is expressed, whereby long chain polyunsaturated fatty acid biosynthesis in the cells is altered.

The present invention is further directed to the use of chain polyunsaturated fatty acid selected from the group consisting of ARA, DGLA and EPA.

The present invention is further directed toward pharmaceutical compositions comprising at least one nutrient selected from the group consisting of a vitamin, a mineral, a carbohydrate, a sugar, an amino acid, a free fatty acid, a phospholipid, an antioxidant, and a phenolic compound.

Brief Description of the Drawings

Figure 1 shows possible pathways for the synthesis of arachidonic acid (20:4 Δ5, 8, 11, 14) and stearidonic acid (18:4 Δ6, 9, 12, 15) from palmitic acid (C_{16}) from a variety of organisms, including algae, *Mortierella* and humans. These PUFAs can serve as precursors to other molecules important for humans and other animals, including prostacyclins, leukotrienes, and prostaglandins, some of which are shown.

Figure 2 shows possible pathways for production of PUFAs in addition to ARA, including EPA and DHA, for a variety of organisms.

Figure 3A-D shows the DNA sequence of the *Mortierella alpina* Δ5-desaturase and the deduced amino acid sequence.

Figure 4 shows the deduced amino acid sequence of the PCR fragment (see Example 1)

Figure 5A and 5B show alignments of the protein sequence of the Δ5-desaturase with Δ6-desaturases.

Figure 6A and 6B show the effect of the timing of substrate addition relative to induction on conversion of substrate to product in SC334 containing the Δ5-desaturase gene.

Figure 7A and 7B show the effect of inducer concentration on Δ5-desaturase expression in SC334.

Figure 8A and 8B show the effect of induction temperature on Δ5-desaturase activity in SC334.

Figure 9A and 9B show the effect of host strain on the conversion of substrate to product in strains expressing the Δ5-desaturase gene at 15°C.

Figure 10A and 10B show the effect of host strain on the conversion of substrate to product in strains expressing the Δ5-desaturase gene at 30°C.

Figure 11 shows the effect of a host strain expressing choline transferase as well as the Δ5-desaturase gene on the conversion of substrate to product.

Figure 12A and 12B show the effect of media composition and temperature on the conversion of substrate to product in two host strains expressing the Δ5-desaturase gene.

Figure 13 shows alignment of the protein sequence of Ma 29 and contig 253538a.

Figure 14 shows alignment of the protein sequence of Ma 524 and contig 253538a.

Brief Description of the Sequence Listings

SEQ ID NO:1 shows a DNA sequence of the *Mortierella alpina* Δ5-desaturase.

SEQ ID NO:2 shows an amino acid sequence of *Mortierella alpina* Δ5-desaturase.

SEQ ID NO: 3 shows the deduced amino acid sequence of the *M. alpina* PCR fragment (see Example 1).

SEQ ID NO: 4 - SEQ ID NO: 7 show the deduced amino acid sequences of various Δ6-desaturases.

SEQ ID NO: 8 and SEQ ID NO: 9 show PCR primer sequences for Δ6-desaturases

SEQ ID NO: 10 shows a primer for reverse transcription of total RNA.

SEQ ID NO: 11 and SEQ ID NO: 12 show amino acid motifs for desaturase sequences.

SEQ ID NO: 13 and SEQ ID NO: 14 show the nucleotide and amino acid sequence of a *Dictyostelium discoideum* desaturase sequence.

SEQ ID NO: 15 and SEQ ID NO: 16 show the nucleotide and amino acid sequence of a *Phaeodactylum tricornutum* desaturase sequence.

SEQ ID NO: 17-20 show the nucleotide and deduced amino acid sequence of a Schizochytrium cDNA clone.

SEQ ID NO: 21-27 show nucleotide sequences for human desaturases.

SEQ ID NO: 28 - SEQ ID NO: 34 show peptide sequences for human desaturases.

Detailed Description of the Invention

In order to ensure a complete understanding of the invention, the following definitions are provided:

Δ5-Desaturase: Δ5 desaturase is an enzyme which introduces a double bond between carbons 5 and 6 from the carboxyl end of a fatty acid molecule.

Δ6-Desaturase: Δ6-desaturase is an enzyme which introduces a double bond between carbons 6 and 7 from the carboxyl end of a fatty acid molecule.

Δ9-Desaturase: Δ9-desaturase is an enzyme which introduces a double bond between carbons 9 and 10 from the carboxyl end of a fatty acid molecule.

Δ12-Desaturase: Δ12-desaturase is an enzyme which introduces a double bond between carbons 12 and 13 from the carboxyl end of a fatty acid molecule.

Fatty Acids: Fatty acids are a class of compounds containing a long hydrocarbon chain and a terminal carboxylate group. Fatty acids include the following:

Fatty Acid		
12:0	lauric acid	
16:0	palmitic acid	
16:1	palmitoleic acid	

Fatty Acid		
18:0	stearic acid	
18:1	oleic acid	Δ9-18:1
18:2 Δ5,9	taxoleic acid	Δ5,9-18:2
18:2 Δ6,9	6,9-octadecadienoic acid	Δ6,9-18:2
18:2	linoleic acid	Δ9,12-18:2 (LA)
18:3 Δ6,9,12	gamma-linolenic acid	Δ6,9,12-18:3 (GLA)
18:3 Δ5,9,12	pinolenic acid	Δ5,9,12-18:3
18:3	alpha-linolenic acid	Δ9,12,15-18:3 (ALA)
18:4	stearidonic acid	Δ6,9,12,15-18:4 (SDA)
20:0	Arachidic acid	
20:1	Eicoscenic Acid	
22:0	behehic acid	
22:1	erucic acid	
22:2	Docasadienoic acid	
20:4 ω6	arachidonic acid	Δ5,8,11,14-20:4 (ARA)
20:3 ω6	ω6-eicosatrienoic dihomo-gamma linolenic	Δ8,11,14-20:3 (DGLA)
20:5 ω3	Eicosapentanoic (Timnodonic acid)	Δ5,8,11,14,17-20:5 (EPA)
20:3 ω3	ω3-eicosatrienoic	Δ11,16,17-20:3
20:4 ω3	ω3-eicosatetraenoic	Δ8,11,14,17-20:4
22:5 ω3	Docasapentaenoic	Δ7,10,13,16,19-22:5 (ω3DPA)
22:6 ω3	Docosahexaenoic (cervonic acid)	Δ4,7,10,13,16,19-22:6 (DHA)
24:0	Lignoceric acid	

Taking into account these definitions, the present invention is directed to novel DNA sequences, DNA constructs, methods and compositions are provided which permit modification of the poly-unsaturated long chain fatty acid content of, for example, microbial cells or animals. Host cells are manipulated to express a sense or antisense transcript of a DNA encoding a polypeptide(s) which catalyzes the conversion of DGLA to ARA. The substrate(s) for the expressed enzyme may be produced by the host cell or may be exogenously supplied. To achieve expression, the transformed DNA is

operably associated with transcriptional and translational initiation and termination regulatory regions that are functional in the host cell. Constructs comprising the gene to be expressed can provide for integration into the genome of the host cell or can autonomously replicate in the host cell. For production of ARA, the expression cassettes generally used include a cassette which provides for Δ5-desaturase activity, particularly in a host cell which produces or can take up DGLA. Production of ω6-type unsaturated fatty acids, such as ARA, is favored in a host microorganism or animal which is substantially free of ALA. The host is selected or obtained by removing or inhibiting activity of a Δ15- or ω3- type desaturase (see Figure 2). The endogenous desaturase activity can be affected by providing an expression cassette for an antisense Δ15 or ω3 transcript, by disrupting a target Δ15- or ω3-desaturase gene through insertion, substitution and/or deletion of all or part of the target gene, or by adding a Δ15- or ω3-desaturase inhibitor. Production of LA also can be increased by providing expression cassettes for Δ9 and/or Δ12-desaturases where their respective enzymatic activities are limiting.

MICROBIAL PRODUCTION OF FATTY ACIDS

Microbial production of fatty acids has several advantages over purification from natural sources such as fish or plants. Many microbes are known with greatly simplified oil compositions compared with those of higher organisms, making purification of desired components easier. Microbial production is not subject to fluctuations caused by external variables such as weather and food supply. Microbially produced oil is substantially free of contamination by environmental pollutants. Additionally, microbes can provide PUFAs in particular forms which may have specific uses. For example, *Spirulina* can provide PUFAs predominantly at the first and third positions of triglycerides; digestion by pancreatic lipases preferentially releases fatty acids from these positions. Following human or animal ingestion of triglycerides derived from *Spirulina*, these PUFAs are released by pancreatic lipases as free

fatty acids and thus are directly available, for example, for infant brain development. Additionally, microbial oil production can be manipulated by controlling culture conditions, notably by providing particular substrates for microbially expressed enzymes, or by addition of compounds which suppress undesired biochemical pathways. In addition to these advantages, production of fatty acids from recombinant microbes provides the ability to alter the naturally occurring microbial fatty acid profile by providing new synthetic pathways in the host or by suppressing undesired pathways, thereby increasing levels of desired PUFAs, or conjugated forms thereof, and decreasing levels of undesired PUFAs.

PRODUCTION OF FATTY ACIDS IN ANIMALS

Production of fatty acids in animals also presents several advantages. Expression of desaturase genes in animals can produce greatly increased levels of desired PUFAs in animal tissues, making recovery from those tissues more economical. For example, where the desired PUFAs are expressed in the breast milk of animals, methods of isolating PUFAs from animal milk are well established. In addition to providing a source for purification of desired PUFAs, animal breast milk can be manipulated through expression of desaturase genes, either alone or in combination with other human genes, to provide animal milks with a PUFA composition substantially similar to human breast milk during the different stages of infant development. Humanized animal milks could serve as infant formulas where human nursing is impossible or undesired, or in cases of malnourishment or disease.

Depending upon the host cell, the availability of substrate, and the desired end product(s), several polypeptides, particularly desaturases, are of interest. By "desaturase" is intended a polypeptide which can desaturate one or more fatty acids to produce a mono- or poly-unsaturated fatty acid or precursor thereof of interest. Of particular interest are polypeptides which can catalyze the conversion of DGLA to produce ARA which includes enzymes which desaturate at the $\Delta5$ position. By "polypeptide" is meant any chain of amino acids, regardless of length or post-translational modification, for example,

glycosylation or phosphorylation. Considerations for choosing a specific polypeptide having desaturase activity include the pH optimum of the polypeptide, whether the polypeptide is a rate limiting enzyme or a component thereof, whether the desaturase used is essential for synthesis of a desired polyunsaturated fatty acid, and/or co-factors required by the polypeptide. The expressed polypeptide preferably has parameters compatible with the biochemical environment of its location in the host cell. For example, the polypeptide may have to compete for substrate with other enzymes in the host cell. Analyses of the K_m and specific activity of the polypeptide in question therefore are considered in determining the suitability of a given polypeptide for modifying PUFA production in a given host cell. The polypeptide used in a particular situation is one which can function under the conditions present in the intended host cell but otherwise can be any polypeptide having desaturase activity which has the desired characteristic of being capable of modifying the relative production of a desired PUFA.

For production of ARA, the DNA sequence used encodes a polypeptide having Δ5-desaturase activity. In particular instances, this can be coupled with an expression cassette which provides for production of a polypeptide having Δ6-desaturase activity and the host cell can optionally be depleted of any Δ15-desaturase activity present, for example by providing a transcription cassette for production of antisense sequences to the Δ15-desaturase transcription product, by disrupting the Δ15-desaturase gene, or by using a host cell which naturally has, or has been mutated to have, low Δ15-desaturase activity. Inhibition of undesired desaturase pathways also can be accomplished through the use of specific desaturase inhibitors such as those described in U.S. Patent No. 4,778,630. The choice of combination of cassettes used can depend in part on the PUFA profile of the host cell. Where the host cell Δ5-desaturase activity is limiting, overexpression of Δ5-desaturase alone generally will be sufficient to provide for enhanced ARA production in the presence of an appropriate substrate such as DGLA. ARA production also can be increased by providing expression cassettes for Δ9- or Δ12-desaturase genes when the activities of

those desaturases are limiting. A scheme for the synthesis of arachidonic acid (20:4 $\Delta^{5, 8, 11, 14}$) from palmitic acid (C_{16}) is shown in Figure 1. A key enzyme in this pathway is a Δ5-desaturase which converts DH-γ-linolenic acid (DGLA, eicosatrienoic acid) to ARA. Conversion of α-linolenic acid (ALA) to stearidonic acid by a Δ6-desaturase is also shown. Production of PUFAs in addition to ARA, including EPA and DHA is shown in Figure 2.

SOURCES OF POLYPEPTIDES HAVING DESATURASE ACTIVITY

A source of polypeptides having desaturase activity and oligonucleotides encoding such polypeptides are organisms which produce a desired polyunsaturated fatty acid. As an example, microorganisms having an ability to produce ARA can be used as a source of Δ5-desaturase activity. Such microorganisms include, for example, those belonging to the genera *Mortierella, Conidiobolus, Pythium, Phytophathora, Penicillium, Porphyridium, Coidosporium, Mucor, Fusarium, Aspergillus, Rhodotorula,* and *Entomophthora*. Within the genus *Porphyridium*, of particular interest is *Porphyridium cruentum*. Within the genus *Mortierella*, of particular interest are *Mortierella elongata, Mortierella exigua, Mortierella hygrophila, Mortierella ramanniana*, var. angulispora, and *Mortierella alpina*. Within the genus *Mucor*, of particular interest are *Mucor circinelloides* and *Mucor javanicus*.

DNAs encoding desired desaturases can be identified in a variety of ways. As an example, a source of the desired desaturase, for example genomic or cDNA libraries from *Mortierella*, is screened with detectable enzymatically- or chemically-synthesized probes, which can be made from DNA, RNA, or non-naturally occurring nucleotides, or mixtures thereof. Probes may be enzymatically synthesized from DNAs of known desaturases for normal or reduced-stringency hybridization methods. Oligonucleotide probes also can be used to screen sources and can be based on sequences of known desaturases, including sequences conserved among known desaturases, or on peptide sequences obtained from the desired purified protein. Oligonucleotide probes based on amino acid sequences can be degenerate to encompass the degeneracy

of the genetic code, or can be biased in favor of the preferred codons of the source organism. Oligonucleotides also can be used as primers for PCR from reverse transcribed mRNA from a known or suspected source; the PCR product can be the full length cDNA or can be used to generate a probe to obtain the desired full length cDNA. Alternatively, a desired protein can be entirely sequenced and total synthesis of a DNA encoding that polypeptide performed.

Once the desired genomic or cDNA has been isolated, it can be sequenced by known methods. It is recognized in the art that such methods are subject to errors, such that multiple sequencing of the same region is routine and is still expected to lead to measurable rates of mistakes in the resulting deduced sequence, particularly in regions having repeated domains, extensive secondary structure, or unusual base compositions, such as regions with high GC base content. When discrepancies arise, resequencing can be done and can employ special methods. Special methods can include altering sequencing conditions by using: different temperatures; different enzymes; proteins which alter the ability of oligonucleotides to form higher order structures; altered nucleotides such as ITP or methylated dGTP; different gel compositions, for example adding formamide; different primers or primers located at different distances from the problem region; or different templates such as single stranded DNAs. Sequencing of mRNA also can be employed.

For the most part, some or all of the coding sequence for the polypeptide having desaturase activity is from a natural source. In some situations, however, it is desirable to modify all or a portion of the codons, for example, to enhance expression, by employing host preferred codons. Host preferred codons can be determined from the codons of highest frequency in the proteins expressed in the largest amount in a particular host species of interest. Thus, the coding sequence for a polypeptide having desaturase activity can be synthesized in whole or in part. All or portions of the DNA also can be synthesized to remove any destabilizing sequences or regions of secondary structure which would be present in the transcribed mRNA. All or portions of the DNA also can be synthesized to alter the base composition to one more

preferable in the desired host cell. Methods for synthesizing sequences and bringing sequences together are well established in the literature. *In vitro* mutagenesis and selection, site-directed mutagenesis, or other means can be employed to obtain mutations of naturally occurring desaturase genes to produce a polypeptide having desaturase activity *in vivo* with more desirable physical and kinetic parameters for function in the host cell, such as a longer half-life or a higher rate of production of a desired polyunsaturated fatty acid.

Mortierella alpina **Desaturase**

Of particular interest is the *Mortierella alpina* Δ5-desaturase which has 446 amino acids; the amino acid sequence is shown in Figure 3. The gene encoding the *Mortierella alpina* Δ5-desaturase can be expressed in transgenic microorganisms or animals to effect greater synthesis of ARA from DGLA. Other DNAs which are substantially identical to the *Mortierella alpina* Δ5-desaturase DNA, or which encode polypeptides which are substantially identical to the *Mortierella alpina* Δ5-desaturase polypeptide, also can be used. By substantially identical is intended an amino acid sequence or nucleic acid sequence exhibiting in order of increasing preference at least 60%, 80%, 90% or 95% homology to the *Mortierella alpina* Δ5-desaturase amino acid sequence or nucleic acid sequence encoding the amino acid sequence. For polypeptides, the length of comparison sequences generally is at least 16 amino acids, preferably at least 20 amino acids, or most preferably 35 amino acids. For nucleic acids, the length of comparison sequences generally is at least 50 nucleotides, preferably at least 60 nucleotides, and more preferably at least 75 nucleotides, and most preferably, 110 nucleotides. Homology typically is measured using sequence analysis software, for example, the Sequence Analysis software package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wisconsin 53705, MEGAlign (DNAStar, Inc., 1228 S. Park St., Madison, Wisconsin 53715), and MacVector (Oxford Molecular Group, 2105 S. Bascom Avenue, Suite 200, Campbell, California 95008). Such software matches similar sequences by

assigning degrees of homology to various substitutions, deletions, and other modifications. Conservative substitutions typically include substitutions within the following groups: glycine and alanine; valine, isoleucine and leucine; aspartic acid, glutamic acid, asparagine, and glutamine; serine and threonine; lysine and arginine; and phenylalanine and tyrosine. Substitutions may also be made on the basis of conserved hydrophobicity or hydrophilicity (Kyte and Doolittle, *J. Mol. Biol.* 157: 105-132, 1982), or on the basis of the ability to assume similar polypeptide secondary structure (Chou and Fasman, *Adv. Enzymol.* 47: 45-148, 1978).

Other Desaturases

Encompassed by the present invention are related desaturases from the same or other organisms. Such related desaturases include variants of the disclosed Δ5-desaturase naturally occurring within the same or different species of *Mortierella*, as well as homologues of the disclosed Δ5-desaturase from other species. Also included are desaturases which, although not substantially identical to the *Mortierella alpina* Δ5-desaturase, desaturate a fatty acid molecule at carbon 5 from the carboxyl end of a fatty acid molecule. Related desaturases can be identified by their ability to function substantially the same as the disclosed desaturases; that is, are still able to effectively convert DGLA to ARA. Related desaturases also can be identified by screening sequence databases for sequences homologous to the disclosed desaturase, by hybridization of a probe based on the disclosed desaturase to a library constructed from the source organism, or by RT-PCR using mRNA from the source organism and primers based on the disclosed desaturase. Such desaturases include those from humans, *Dictyostelium discoideum* and *Phaeodactylum tricornum.*

The regions of a desaturase polypeptide important for desaturase activity can be determined through routine mutagenesis, expression of the resulting mutant polypeptides and determination of their activities. Mutants may include deletions, insertions and point mutations, or combinations thereof. A typical

functional analysis begins with deletion mutagenesis to determine the N- and C-terminal limits of the protein necessary for function, and then internal deletions, insertions or point mutants are made to further determine regions necessary for function. Other techniques such as cassette mutagenesis or total synthesis also can be used. Deletion mutagenesis is accomplished, for example, by using exonucleases to sequentially remove the 5' or 3' coding regions. Kits are available for such techniques. After deletion, the coding region is completed by ligating oligonucleotides containing start or stop codons to the deleted coding region after 5' or 3' deletion, respectively. Alternatively, oligonucleotides encoding start or stop codons are inserted into the coding region by a variety of methods including site-directed mutagenesis, mutagenic PCR or by ligation onto DNA digested at existing restriction sites. Internal deletions can similarly be made through a variety of methods including the use of existing restriction sites in the DNA, by use of mutagenic primers via site directed mutagenesis or mutagenic PCR. Insertions are made through methods such as linker-scanning mutagenesis, site-directed mutagenesis or mutagenic PCR. Point mutations are made through techniques such as site-directed mutagenesis or mutagenic PCR.

Chemical mutagenesis also can be used for identifying regions of a desaturase polypeptide important for activity. A mutated construct is expressed, and the ability of the resulting altered protein to function as a desaturase is assayed. Such structure-function analysis can determine which regions may be deleted, which regions tolerate insertions, and which point mutations allow the mutant protein to function in substantially the same way as the native desaturase. All such mutant proteins and nucleotide sequences encoding them are within the scope of the present invention.

EXPRESSION OF DESATURASE GENES

Once the DNA encoding a desaturase polypeptide has been obtained, it is placed in a vector capable of replication in a host cell, or is propagated *in vitro* by means of techniques such as PCR or long PCR. Replicating vectors can include plasmids, phage, viruses, cosmids and the like. Desirable vectors include those useful for mutagenesis of the gene of interest or for expression of

the gene of interest in host cells. The technique of long PCR has made *in vitro* propagation of large constructs possible, so that modifications to the gene of interest, such as mutagenesis or addition of expression signals, and propagation of the resulting constructs can occur entirely *in vitro* without the use of a replicating vector or a host cell.

For expression of a desaturase polypeptide, functional transcriptional and translational initiation and termination regions are operably linked to the DNA encoding the desaturase polypeptide. Expression of the polypeptide coding region can take place *in vitro* or in a host cell. Transcriptional and translational initiation and termination regions are derived from a variety of nonexclusive sources, including the DNA to be expressed, genes known or suspected to be capable of expression in the desired system, expression vectors, chemical synthesis, or from an endogenous locus in a host cell.

Expression In Vitro

In vitro expression can be accomplished, for example, by placing the coding region for the desaturase polypeptide in an expression vector designed for *in vitro* use and adding rabbit reticulocyte lysate and cofactors; labeled amino acids can be incorporated if desired. Such *in vitro* expression vectors may provide some or all of the expression signals necessary in the system used. These methods are well known in the art and the components of the system are commercially available. The reaction mixture can then be assayed directly for the polypeptide, for example by determining its activity, or the synthesized polypeptide can be purified and then assayed.

Expression In A Host Cell

Expression in a host cell can be accomplished in a transient or stable fashion. Transient expression can occur from introduced constructs which contain expression signals functional in the host cell, but which constructs do not replicate and rarely integrate in the host cell, or where the host cell is not proliferating. Transient expression also can be accomplished by inducing the

activity of a regulatable promoter operably linked to the gene of interest, although such inducible systems frequently exhibit a low basal level of expression. Stable expression can be achieved by introduction of a construct that can integrate into the host genome or that autonomously replicates in the host cell. Stable expression of the gene of interest can be selected for through the use of a selectable marker located on or transfected with the expression construct, followed by selection for cells expressing the marker. When stable expression results from integration, integration of constructs can occur randomly within the host genome or can be targeted through the use of constructs containing regions of homology with the host genome sufficient to target recombination with the host locus. Where constructs are targeted to an endogenous locus, all or some of the transcriptional and translational regulatory regions can be provided by the endogenous locus.

When increased expression of the desaturase polypeptide in the source organism is desired, several methods can be employed. Additional genes encoding the desaturase polypeptide can be introduced into the host organism. Expression from the native desaturase locus also can be increased through homologous recombination, for example by inserting a stronger promoter into the host genome to cause increased expression, by removing destabilizing sequences from either the mRNA or the encoded protein by deleting that information from the host genome, or by adding stabilizing sequences to the mRNA (USPN 4,910,141).

When it is desirable to express more than one different gene, appropriate regulatory regions and expression methods, introduced genes can be propagated in the host cell through use of replicating vectors or by integration into the host genome. Where two or more genes are expressed from separate replicating vectors, it is desirable that each vector has a different means of replication. Each introduced construct, whether integrated or not, should have a different means of selection and should lack homology to the other constructs to maintain stable expression and prevent reassortment of elements among constructs. Judicious choices of regulatory regions, selection means and method of

propagation of the introduced construct can be experimentally determined so that all introduced genes are expressed at the necessary levels to provide for synthesis of the desired products.

As an example, where the host cell is a yeast, transcriptional and translational regions functional in yeast cells are provided, particularly from the host species. The transcriptional initiation regulatory regions can be obtained, for example from genes in the glycolytic pathway, such as alcohol dehydrogenase, glyceraldehyde-3-phosphate dehydrogenase (GPD), phosphoglucoisomerase, phosphoglycerate kinase, etc. or regulatable genes such as acid phosphatase, lactase, metallothionein, glucoamylase, etc. Any one of a number of regulatory sequences can be used in a particular situation, depending upon whether constitutive or induced transcription is desired, the particular efficiency of the promoter in conjunction with the open-reading frame of interest, the ability to join a strong promoter with a control region from a different promoter which allows for inducible transcription, ease of construction, and the like. Of particular interest are promoters which are activated in the presence of galactose. Galactose-inducible promoters (GAL1, GAL7, and GAL10) have been extensively utilized for high level and regulated expression of protein in yeast (Lue *et al.*, *Mol. Cell. Biol.* Vol. 7, p. 3446, 1987; Johnston, *Microbiol. Rev.* Vol. 51, p. 458, 1987). Transcription from the GAL promoters is activated by the GAL4 protein, which binds to the promoter region and activates transcription when galactose is present. In the absence of galactose, the antagonist GAL80 binds to GAL4 and prevents GAL4 from activating transcription. Addition of galactose prevents GAL80 from inhibiting activation by GAL4.

Nucleotide sequences surrounding the translational initiation codon ATG have been found to affect expression in yeast cells. If the desired polypeptide is poorly expressed in yeast, the nucleotide sequences of exogenous genes can be modified to include an efficient yeast translation initiation sequence to obtain optimal gene expression. For expression in *Saccharomyces*, this can be done by site-directed mutagenesis of an inefficiently expressed gene

by fusing it in-frame to an endogenous *Saccharomyces* gene, preferably a highly expressed gene, such as the lactase gene.

The termination region can be derived from the 3' region of the gene from which the initiation region was obtained or from a different gene. A large number of termination regions are known to and have been found to be satisfactory in a variety of hosts from the same and different genera and species. The termination region usually is selected more as a matter of convenience rather than because of any particular property. Preferably, the termination region is derived from a yeast gene, particularly *Saccharomyces*, *Schizosaccharomyces*, *Candida* or *Kluyveromyces*. The 3' regions of two mammalian genes, γ interferon and $\alpha 2$ interferon, are also known to function in yeast.

INTRODUCTION OF CONSTRUCTS INTO HOST CELLS

Constructs comprising the gene of interest may be introduced into a host cell by standard techniques. These techniques include transformation, protoplast fusion, lipofection, transfection, transduction, conjugation, infection, bolistic impact, electroporation, microinjection, scraping, or any other method which introduces the gene of interest into the host cell. Methods of transformation which are used include lithium acetate transformation (*Methods in Enzymology*, Vol. 194, p. 186-187, 1991). For convenience, a host cell which has been manipulated by any method to take up a DNA sequence or construct will be referred to as "transformed" or "recombinant" herein.

The subject host will have at least have one copy of the expression construct and may have two or more, depending upon whether the gene is integrated into the genome, amplified, or is present on an extrachromosomal element having multiple copy numbers. Where the subject host is a yeast, four principal types of yeast plasmid vectors can be used: Yeast Integrating plasmids (YIps), Yeast Replicating plasmids (YRps), Yeast Centromere plasmids (YCps), and Yeast Episomal plasmids (YEps). YIps lack a yeast replication origin and must be propagated as integrated elements in the yeast genome. YRps have a chromosomally derived autonomously replicating sequence and

are propagated as medium copy number (20 to 40), autonomously replicating, unstably segregating plasmids. YCps have both a replication origin and a centromere sequence and propagate as low copy number (10-20), autonomously replicating, stably segregating plasmids. YEps have an origin of replication from the yeast 2μm plasmid and are propagated as high copy number, autonomously replicating, irregularly segregating plasmids. The presence of the plasmids in yeast can be ensured by maintaining selection for a marker on the plasmid. Of particular interest are the yeast vectors pYES2 (a YEp plasmid available from Invitrogen, confers uracil prototrophy and a GAL1 galactose-inducible promoter for expression), pRS425-pG1 (a YEp plasmid obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University, containing a constitutive GPD promoter and conferring leucine prototrophy), and pYX424 (a YEp plasmid having a constitutive TP1 promoter and conferring leucine prototrophy; Alber, T. and Kawasaki, G. (1982). *J. Mol. & Appl. Genetics* 1: 419).

The transformed host cell can be identified by selection for a marker contained on the introduced construct. Alternatively, a separate marker construct may be introduced with the desired construct, as many transformation techniques introduce many DNA molecules into host cells. Typically, transformed hosts are selected for their ability to grow on selective media. Selective media may incorporate an antibiotic or lack a factor necessary for growth of the untransformed host, such as a nutrient or growth factor. An introduced marker gene therefor may confer antibiotic resistance, or encode an essential growth factor or enzyme, and permit growth on selective media when expressed in the transformed host. Selection of a transformed host also can occur when the expressed marker protein can be detected, either directly or indirectly. The marker protein may be expressed alone or as a fusion to another protein. The marker protein can be detected by its enzymatic activity; for example β galactosidase can convert the substrate X-gal to a colored product, and luciferase can convert luciferin to a light-emitting product. The marker protein can be detected by its light-producing or modifying characteristics; for

example, the green fluorescent protein of *Aequorea victoria* fluoresces when illuminated with blue light. Antibodies can be used to detect the marker protein or a molecular tag on, for example, a protein of interest. Cells expressing the marker protein or tag can be selected, for example, visually, or by techniques such as FACS or panning using antibodies. For selection of yeast transformants, any marker that functions in yeast may be used. Desirably, resistance to kanamycin and the amino glycoside G418 are of interest, as well as ability to grow on media lacking uracil, leucine, lysine or tryptophan.

The Δ5-desaturase-mediated production of PUFAs can be performed in either prokaryotic or eukaryotic host cells. Prokaryotic cells of interest include *Eschericia*, *Bacillus*, *Lactobacillus*, *cyanobacteria* and the like. Eukaryotic cells include mammalian cells such as those of lactating animals, avian cells such as of chickens, and other cells amenable to genetic manipulation including insect, fungal, and algae cells. The cells may be cultured or formed as part or all of a host organism including an animal. Viruses and bacteriophage also may be used with the cells in the production of PUFAs, particularly for gene transfer, cellular targeting and selection. In a preferred embodiment, the host is any microorganism or animal which produces DGLA and/or can assimilate exogenously supplied DGLA, and preferably produces large amounts of DGLA. Examples of host animals include mice, rats, rabbits, chickens, quail, turkeys, bovines, sheep, pigs, goats, yaks, etc., which are amenable to genetic manipulation and cloning for rapid expansion of the transgene expressing population. For animals, a Δ5-desaturase transgene can be adapted for expression in target organelles, tissues and body fluids through modification of the gene regulatory regions. Of particular interest is the production of PUFAs in the breast milk of the host animal.

Expression In Yeast

Examples of host microorganisms include *Saccharomyces cerevisiae*, *Saccharomyces carlsbergensis*, or other yeast such as *Candida, Kluyveromyces* or other fungi, for example, filamentous fungi such as *Aspergillus, Neurospora,*

Penicillium, etc. Desirable characteristics of a host microorganism are, for example, that it is genetically well characterized, can be used for high level expression of the product using ultra-high density fermentation, and is on the GRAS (generally recognized as safe) list since the proposed end product is intended for ingestion by humans. Of particular interest is use of a yeast, more particularly baker's yeast (*S. cerevisiae*), as a cell host in the subject invention. Strains of particular interest are SC334 (Mat α pep4-3 prbl-1122 ura3-52 leu2-3, 112 regl-501 gal1; *Gene* 83:57-64, 1989, Hovland P. *et al.*), YTC34 (α ade2-101 his3Δ200 lys2-801 ura3-52; obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University), YTC41 (a/α ura3-52/ura3=52 lys2-801/lys2-801 ade2-101/ade2-101 trp1-Δ1/trp1-Δ1 his3Δ200/his3Δ200 leu2Δ1/leu2Δ1; obtained from Dr. T. H. Chang, Ass. Professor of Molecular Genetics, Ohio State University), BJ1995 (obtained from the Yeast Genetic Stock Centre, 1021 Donner Laboratory, Berkeley, CA 94720), INVSC1 (Mat α hiw3Δ1 leu2 trp1-289 ura3-52; obtained from Invitrogen, 1600 Faraday Ave., Carlsbad, CA 92008) and INVSC2 (Mat α his3Δ200 ura3-167; obtained from Invitrogen).

Expression In Avian Species

For producing PUFAs in avian species and cells, such as chickens, turkeys, quail and ducks, gene transfer can be performed by introducing a nucleic acid sequence encoding a Δ5-desaturase into the cells following procedures known in the art. If a transgenic animal is desired, pluripotent stem cells of embryos can be provided with a vector carrying a Δ5-desaturase encoding transgene and developed into adult animal (USPN 5,162,215; Ono *et al.* (1996) *Comparative Biochemistry and Physiology A 113*(3):287-292; WO 9612793; WO 9606160). In most cases, the transgene will be modified to express high levels of the desaturase in order to increase production of PUFAs. The transgene can be modified, for example, by providing transcriptional and/or translational regulatory regions that function in avian cells, such as promoters which direct expression in particular tissues and egg parts such as yolk. The

gene regulatory regions can be obtained from a variety of sources, including chicken anemia or avian leukosis viruses or avian genes such as a chicken ovalbumin gene.

Expression In Insect Cells

Production of PUFAs in insect cells can be conducted using baculovirus expression vectors harboring a Δ5-desaturase transgene. Baculovirus expression vectors are available from several commercial sources such as Clonetech. Methods for producing hybrid and transgenic strains of algae, such as marine algae, which contain and express a desaturase transgene also are provided. For example, transgenic marine algae may be prepared as described in USPN 5,426,040. As with the other expression systems described above, the timing, extent of expression and activity of the desaturase transgene can be regulated by fitting the polypeptide coding sequence with the appropriate transcriptional and translational regulatory regions selected for a particular use. Of particular interest are promoter regions which can be induced under preselected growth conditions. For example, introduction of temperature sensitive and/or metabolite responsive mutations into the desaturase transgene coding sequences, its regulatory regions, and/or the genome of cells into which the transgene is introduced can be used for this purpose.

Expression In Plants

Production of PUFA's in plants can be conducted using various plant transformation systems such as the use of *Agrobacterium tumefaciens*, plant viruses, particle cell transformation and the like which are disclosed in Applicant's related applications U.S. Application Serial Nos. 08/834,033 and 08/956,985 and continuation-in-part applications filed simultaneously with this application all of which are hereby incorporated by reference.

The transformed host cell is grown under appropriate conditions adapted for a desired end result. For host cells grown in culture, the conditions are

typically optimized to produce the greatest or most economical yield of PUFAs, which relates to the selected desaturase activity. Media conditions which may be optimized include: carbon source, nitrogen source, addition of substrate, final concentration of added substrate, form of substrate added, aerobic or anaerobic growth, growth temperature, inducing agent, induction temperature, growth phase at induction, growth phase at harvest, pH, density, and maintenance of selection. Microorganisms such as yeast, for example, are preferably grown using selected media of interest, which include yeast peptone broth (YPD) and minimal media (contains amino acids, yeast nitrogen base, and ammonium sulfate, and lacks a component for selection, for example uracil). Desirably, substrates to be added are first dissolved in ethanol. Where necessary, expression of the polypeptide of interest may be induced, for example by including or adding galactose to induce expression from a GAL promoter.

Expression In An Animal

Expression in cells of a host animal can likewise be accomplished in a transient or stable manner. Transient expression can be accomplished via known methods, for example infection or lipofection, and can be repeated in order to maintain desired expression levels of the introduced construct (*see* Ebert, PCT publication WO 94/05782). Stable expression can be accomplished via integration of a construct into the host genome, resulting in a transgenic animal. The construct can be introduced, for example, by microinjection of the construct into the pronuclei of a fertilized egg, or by transfection, retroviral infection or other techniques whereby the construct is introduced into a cell line which may form or be incorporated into an adult animal (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Wilmut *et al.* (1997) *Nature* 385:810). The recombinant eggs or embryos are transferred to a surrogate mother (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Wilmut *et al.* (supra)).

After birth, transgenic animals are identified, for example, by the presence of an introduced marker gene, such as for coat color, or by PCR or Southern blotting from a blood, milk or tissue sample to detect the introduced construct, or by an immunological or enzymological assay to detect the expressed protein or the products produced therefrom (U.S. Patent No. 4,873,191; U.S. Patent No. 5,530,177; U.S. Patent No. 5,565,362; U.S. Patent No. 5,366,894; Wilmut *et al.* (supra)). The resulting transgenic animals may be entirely transgenic or may be mosaics, having the transgenes in only a subset of their cells. The advent of mammalian cloning, accomplished by fusing a nucleated cell with an enucleated egg, followed by transfer into a surrogate mother, presents the possibility of rapid, large-scale production upon obtaining a "founder" animal or cell comprising the introduced construct; prior to this, it was necessary for the transgene to be present in the germ line of the animal for propagation (Wilmut *et al.* (supra)).

Expression in a host animal presents certain efficiencies, particularly where the host is a domesticated animal. For production of PUFAs in a fluid readily obtainable from the host animal, such as milk, the desaturase transgene can be expressed in mammary cells from a female host, and the PUFA content of the host cells altered. The desaturase transgene can be adapted for expression so that it is retained in the mammary cells, or secreted into milk, to form the PUFA reaction products localized to the milk (PCT publication WO 95/24488). Expression can be targeted for expression in mammary tissue using specific regulatory sequences, such as those of bovine α-lactalbumin, α-casein, β-casein, γ-casein, κ-casein, β-lactoglobulin, or whey acidic protein, and may optionally include one or more introns and/or secretory signal sequences (U.S. Patent No. 5,530,177; Rosen, U.S. Patent No. 5,565,362; Clark *et al.*, U.S. Patent No. 5,366,894; Garner *et al.*, PCT publication WO 95/23868). Expression of desaturase transgenes, or antisense desaturase transcripts, adapted in this manner can be used to alter the levels of specific PUFAs, or derivatives thereof, found in the animals milk. Additionally, the Δ5-desaturase transgene can be expressed either by itself or with other transgenes, in order to produce

animal milk containing higher proportions of desired PUFAs or PUFA ratios and concentrations that resemble human breast milk (Prieto *et al.*, PCT publication WO 95/24494).

PURIFICATION OF FATTY ACIDS

The fatty acids desaturated in the Δ5 position may be found in the host microorganism or animal as free fatty acids or in conjugated forms such as acylglycerols, phospholipids, sulfolipids or glycolipids, and may be extracted from the host cell through a variety of means well-known in the art. Such means may include extraction with organic solvents, sonication, supercritical fluid extraction using for example carbon dioxide, and physical means such as presses, or combinations thereof. Of particular interest is extraction with methanol and chloroform. Where desirable, the aqueous layer can be acidified to protonate negatively charged moieties and thereby increase partitioning of desired products into the organic layer. After extraction, the organic solvents can be removed by evaporation under a stream of nitrogen. When isolated in conjugated forms, the products may be enzymatically or chemically cleaved to release the free fatty acid or a less complex conjugate of interest, and can then be subject to further manipulations to produce a desired end product. Desirably, conjugated forms of fatty acids are cleaved with potassium hydroxide.

If further purification is necessary, standard methods can be employed. Such methods may include extraction, treatment with urea, fractional crystallization, HPLC, fractional distillation, silica gel chromatography, high speed centrifugation or distillation, or combinations of these techniques. Protection of reactive groups, such as the acid or alkenyl groups, may be done at any step through known techniques, for example alkylation or iodination. Methods used include methylation of the fatty acids to produce methyl esters. Similarly, protecting groups may be removed at any step. Desirably, purification of fractions containing ARA, DHA and EPA may be accomplished by treatment with urea and/or fractional distillation.

USES OF FATTY ACIDS

There are several uses for fatty acids of the subject invention. Probes based on the DNAs of the present invention may find use in methods for isolating related molecules or in methods to detect organisms expressing desaturases. When used as probes, the DNAs or oligonucleotides must be detectable. This is usually accomplished by attaching a label either at an internal site, for example via incorporation of a modified residue, or at the 5' or 3' terminus. Such labels can be directly detectable, can bind to a secondary molecule that is detectably labeled, or can bind to an unlabelled secondary molecule and a detectably labeled tertiary molecule; this process can be extended as long as is practical to achieve a satisfactorily detectable signal without unacceptable levels of background signal. Secondary, tertiary, or bridging systems can include use of antibodies directed against any other molecule, including labels or other antibodies, or can involve any molecules which bind to each other, for example a biotin-streptavidin/avidin system. Detectable labels typically include radioactive isotopes, molecules which chemically or enzymatically produce or alter light, enzymes which produce detectable reaction products, magnetic molecules, fluorescent molecules or molecules whose fluorescence or light-emitting characteristics change upon binding. Examples of labelling methods can be found in USPN 5,011,770. Alternatively, the binding of target molecules can be directly detected by measuring the change in heat of solution on binding of probe to target via isothermal titration calorimetry, or by coating the probe or target on a surface and detecting the change in scattering of light from the surface produced by binding of target or probe, respectively, as may be done with the BIAcore system.

PUFAs produced by recombinant means find applications in a wide variety of areas. Supplementation of humans or animals with PUFAs in various forms can result in increased levels not only of the added PUFAs, but of their metabolic progeny as well. For example, where the inherent Δ5-desaturase pathway is dysfunctional in an individual, treatment with ARA can result not

only in increased levels of ARA, but also of downstream products of ARA such as prostaglandins (see Figure 1). Complex regulatory mechanisms can make it desirable to combine various PUFAs, or to add different conjugates of PUFAs, in order to prevent, control or overcome such mechanisms to achieve the desired levels of specific PUFAs in an individual.

NUTRITIONAL COMPOSITIONS

The present invention also includes nutritional compositions. Such compositions, for purposes of the present invention, include any food or preparation for human consumption including for enteral or parenteral consumption, which when taken into the body (a) serve to nourish or build up tissues or supply energy and/or (b) maintain, restore or support adequate nutritional status or metabolic function.

The nutritional composition of the present invention comprises at least one oil or acid produced in accordance with the present invention and may either be in a solid or liquid form. Additionally, the composition may include edible macronutrients, vitamins and minerals in amounts desired for a particular use. The amount of such ingredients will vary depending on whether the composition is intended for use with normal, healthy infants, children or adults having specialized needs such as those which accompany certain metabolic conditions (e.g., metabolic disorders).

Examples of macronutrients which may be added to the composition include but are not limited to edible fats, carbohydrates and proteins. Examples of such edible fats include but are not limited to coconut oil, soy oil, and mono- and diglycerides. Examples of such carbohydrates include but are not limited to glucose, edible lactose and hydrolyzed search. Additionally, examples of proteins which may be utilized in the nutritional composition of the invention include but are not limited to soy proteins, electrodialysed whey , electrodialysed skim milk, milk whey, or the hydrolysates of these proteins.

With respect to vitamins and minerals, the following may be added to the nutritional compositions of the present invention: calcium, phosphorus,

potassium, sodium, chloride, magnesium, manganese, iron, copper, zinc, selenium, iodine, and Vitamins A, E, D, C, and the B complex. Other such vitamins and minerals may also be added.

The components utilized in the nutritional compositions of the present invention will of semi-purified or purified origin. By semi-purified or purified is meant a material which has been prepared by purification of a natural material or by synthesis.

Examples of nutritional compositions of the present invention include but are not limited to infant formulas, dietary supplements, and rehydration compositions. Nutritional compositions of particular interest include but are not limited to those utilized for enteral and parenteral supplementation for infants, specialist infant formulae, supplements for the elderly, and supplements for those with gastrointestinal difficulties and/or malabsorption.

Nutritional Compositions

A typical nutritional composition of the present invention will contain edible macronutrients, vitamins and minerals in amounts desired for a particular use. The amounts of such ingredients will vary depending on whether the formulation is intended for use with normal, healthy individuals temporarily exposed to stress, or to subjects having specialized needs due to certain chronic or acute disease states (e.g., metabolic disorders). It will be understood by persons skilled in the art that the components utilized in a nutritional formulation of the present invention are of semi-purified or purified origin. By semi-purified or purified is meant a material that has been prepared by purification of a natural material or by synthesis. These techniques are well known in the art (See, e.g., Code of Federal Regulations for Food Ingredients and Food Processing; Recommended Dietary Allowances, 10th Ed., National Academy Press, Washington, D.C., 1989).

In a preferred embodiment, a nutritional formulation of the present invention is an enteral nutritional product, more preferably an adult or child

enteral nutritional product. Accordingly in a further aspect of the invention, a nutritional formulation is provided that is suitable for feeding adults, who are experiencing stress. The formula comprises, in addition to the PUFAs of the invention; macronutrients, vitamins and minerals in amounts designed to provide the daily nutritional requirements of adults.

The macronutritional components include edible fats, carbohydrates and proteins. Exemplary edible fats are coconut oil, soy oil, and mono- and diglycerides and the PUFA oils of this invention. Exemplary carbohydrates are glucose, edible lactose and hydrolyzed cornstarch. A typical protein source would be soy protein, electrodialysed whey or electrodialysed skim milk or milk whey, or the hydrolysates of these proteins, although other protein sources are also available and may be used. These macronutrients would be added in the form of commonly accepted nutritional compounds in amount equivalent to those present in human milk or an energy basis, i.e., on a per calorie basis.

Methods for formulating liquid and enteral nutritional formulas are well known in the art and are described in detail in the examples.

The enteral formula can be sterilized and subsequently utilized on a ready-to-feed (RTF) basis or stored in a concentrated liquid or a powder. The powder can be prepared by spray drying the enteral formula prepared as indicated above, and the formula can be reconstituted by rehydrating the concentrate. Adult and infant nutritional formulas are well known in the art and commercially available (e.g., Similac®, Ensure®, Jevity® and Alimentum® from Ross Products Division, Abbott Laboratories). An oil or acid of the present invention can be added to any of these formulas in the amounts described below.

The energy density of the nutritional composition when in liquid form, can typically range from about 0.6 Kcal to 3.0 Kcal per ml. When in solid or powdered form, the nutritional supplement can contain from about 1.2 to more than 9 Kcals per gm, preferably 3 to 7 Kcals per gram. In general, the osmolality of a liquid product should be less than 700 mOsm and more preferably less than 660 mOsm.

The nutritional formula would typically include vitamins and minerals, in addition to the PUFAs of the invention, in order to help the individual ingest the minimum daily requirements for these substances. In addition to the PUFAs listed above, it may also be desirable to supplement the nutritional composition with zinc, copper, and folic acid in addition to antioxidants. It is believed that these substances will also provide a boost to the stressed immune system and thus will provide further benefits to the individual. The presence of zinc, copper or folic acid is optional and is not required in order to gain the beneficial effects on immune suppression. Likewise a pharmaceutical composition can be supplemented with these same substances as well.

In a more preferred embodiment, the nutritional contains, in addition to the antioxidant system and the PUFA component, a source of carbohydrate wherein at least 5 weight % of said carbohydrate is an indigestible oligosaccharide.. In yet a more preferred embodiment, the nutritional composition additionally contains protein, taurine and carnitine.

The PUFAs, or derivatives thereof, made by the disclosed method can be used as dietary substitutes, or supplements, particularly infant formulas, for patients undergoing intravenous feeding or for preventing or treating malnutrition. Typically, human breast milk has a fatty acid profile comprising from about 0.15 % to about 0.36 % as DHA, from about 0.03 % to about 0.13 % as EPA, from about 0.30 % to about 0.88 % as ARA, from about 0.22 % to about 0.67 % as DGLA, and from about 0.27 % to about 1.04 % as GLA. Additionally, the predominant triglyceride in human milk has been reported to be 1,3-di-oleoyl-2-palmitoyl, with 2-palmitoyl glycerides reported as better absorbed than 2-oleoyl or 2-lineoyl glycerides (USPN 4,876,107). Thus, fatty acids such as ARA, DGLA, GLA and/or EPA produced by the invention can be used to alter the composition of infant formulas to better replicate the PUFA composition of human breast milk. In particular, an oil composition for use in a pharmacologic or food supplement, particularly a breast milk substitute or supplement, will preferably comprise one or more of ARA, DGLA and GLA.

More preferably the oil will comprise from about 0.3 to 30% ARA, from about 0.2 to 30% DGLA, and from about 0.2 to about 30% GLA.

In addition to the concentration, the ratios of ARA, DGLA and GLA can be adapted for a particular given end use. When formulated as a breast milk supplement, or substitute an oil composition which contains two or more of ARA, DGLA and GLA will be provided in a ratio of about 1:19:30 to about 6:1:0.2, respectively. For example, the breast milk of animals can vary in ratios of ARA:DGLA:DGL ranging from 1:19:30 to 6:1:0.2, which includes intermediate ratios which are preferably about 1:1:1, 1:2:1, 1:1:4. When produced together in a host cell, adjusting the rate and percent of conversion of a precursor substrate such as GLA and DGLA to ARA can be used to precisely control the PUFA ratios. For example, a 5% to 10% conversion rate of DGLA to ARA can be used to produce an ARA to DGLA ratio of about 1:19, whereas a conversion rate of about 75% to 80% can be used to produce an ARA to DGLA ratio of about 6:1. Therefore, whether in a cell culture system or in a host animal, regulating the timing, extent and specificity of desaturase expression as described can be used to modulate the PUFA levels and ratios. Depending on the expression system used, e.g., cell culture or an animal expressing oil(s) in its milk, the oils also can be isolated and recombined in the desired concentrations and ratios. Amounts of oils providing these ratios of PUFA can be determined following standard protocols. PUFAs, or host cells containing them, also can be used as animal food supplements to alter an animal's tissue or milk fatty acid composition to one more desirable for human or animal consumption.

For dietary supplementation, the purified PUFAs, or derivatives thereof, may be incorporated into cooking oils, fats or margarines formulated so that in normal use the recipient would receive the desired amount. The PUFAs may also be incorporated into infant formulas, nutritional supplements or other food products, and may find use as anti-inflammatory or cholesterol lowering agents.

Pharmaceutical Compositi ns

The present invention also encompasses a pharmaceutical composition comprising one or more of the acids and/or resulting oils produced in accordance with the methods described herein. More specifically, such a pharmaceutical composition may comprise one or more of the acids and/or oils as well as a standard, well-known, non-toxic pharmaceutically acceptable carrier, adjuvant or vehicle such as, for example, phosphate buffered saline, water, ethanol, polyols, vegetable oils, a wetting agent or an emulsion such as a water/oil emulsion. The composition may be in either a liquid or solid form. For example, the composition may be in the form of a tablet, capsule, ingestible liquid or powder, injectible, or topical ointment or cream.

Possible routes of administration include, for example, oral, rectal and parenteral. The route of administration will, of course, depend upon the desired effect. For example, if the composition is being utilized to treat rough, dry, or aging skin, to treat injured or burned skin, or to treat skin or hair affected by a disease or condition, it may perhaps be applied topically.

The dosage of the composition to be administered to the patient may be determined by one of ordinary skill in the art and depends upon various factors such as weight of the patient, age of the patient, immune status of the patient, etc.

With respect to form, the composition may be, for example, a solution, a dispersion, a suspension, an emulsion or a sterile powder which is then reconstituted.

Additionally, the composition of the present invention may be utilized for cosmetic purposes. It may be added to pre-existing cosmetic compositions such that a mixture is formed or may be used as a sole composition.

Pharmaceutical compositions may be utilized to administer the PUFA component to an individual. Suitable pharmaceutical compositions may comprise physiologically acceptable sterile aqueous or non-aqueous solutions, dispersions, suspensions or emulsions and sterile powders for reconstitution into

sterile solutions or dispersions for ingestion. Examples of suitable aqueous and non-aqueous carriers, diluents, solvents or vehicles include water, ethanol, polyols (propyleneglycol, polyethyleneglycol, glycerol, and the like), suitable mixtures thereof, vegetable oils (such as olive oil) and injectable organic esters such as ethyl oleate. Proper fluidity can be maintained, for example, by the maintenance of the required particle size in the case of dispersions and by the use of surfactants. It may also be desirable to include isotonic agents, for example sugars, sodium chloride and the like. Besides such inert diluents, the composition can also include adjuvants, such as wetting agents, emulsifying and suspending agents, sweetening, flavoring and perfuming agents.

Suspensions, in addition to the active compounds, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth or mixtures of these substances, and the like.

Solid dosage forms such as tablets and capsules can be prepared using techniques well known in the art. For example, PUFAs of the invention can be tableted with conventional tablet bases such as lactose, sucrose, and cornstarch in combination with binders such as acacia, cornstarch or gelatin, disintegrating agents such as potato starch or alginic acid and a lubricant such as stearic acid or magnesium stearate. Capsules can be prepared by incorporating these excipients into a gelatin capsule along with the antioxidants and the PUFA component. The amount of the antioxidants and PUFA component that should be incorporated into the pharmaceutical formulation should fit within the guidelines discussed above.

As used in this application, the term "treat" refers to either preventing, or reducing the incidence of, the undesired occurrence. For example, to treat immune suppression refers to either preventing the occurrence of this suppression or reducing the amount of such suppression. The terms "patient" and "individual" are being used interchangeably and both refer to an animal. The term "animal" as used in this application refers to any warm-blooded

mammal including, but not limited to, dogs, humans, monkeys, and apes. As used in the application the term "about" refers to an amount varying from the stated range or number by a reasonable amount depending upon the context of use. Any numerical number or range specified in the specification should be considered to be modified by the term about.

"Dose" and "serving" are used interchangeably and refer to the amount of the nutritional or pharmaceutical composition ingested by the patient in a single setting and designed to deliver effective amounts of the antioxidants and the structured triglyceride. As will be readily apparent to those skilled in the art, a single dose or serving of the liquid nutritional powder should supply the amount of antioxidants and PUFAs discussed above. The amount of the dose or serving should be a volume that a typical adult can consume in one sitting. This amount can vary widely depending upon the age, weight, sex or medical condition of the patient. However as a general guideline, a single serving or dose of a liquid nutritional produce should be considered as encompassing a volume from 100 to 600 ml, more preferably from 125 to 500 ml and most preferably from 125 to 300 ml.

The PUFAs of the present invention may also be added to food even when supplementation of the diet is not required. For example, the composition may be added to food of any type including but not limited to margarines, modified butters, cheeses, milk, yogurt, chocolate, candy, snacks, salad oils, cooking oils, cooking fats, meats, fish and beverages.

Pharmaceutical Applications

For pharmaceutical use (human or veterinary), the compositions are generally administered orally but can be administered by any route by which they may be successfully absorbed, e.g., parenterally (i.e. subcutaneously, intramuscularly or intravenously), rectally or vaginally or topically, for example, as a skin ointment or lotion. The PUFAs of the present invention may be administered alone or in combination with a pharmaceutically acceptable carrier or excipient. Where available, gelatin capsules are the preferred form of oral administration. Dietary supplementation as set forth above also can

provide an oral route of administration. The unsaturated acids of the present invention may be administered in conjugated forms, or as salts, esters, amides or prodrugs of the fatty acids. Any pharmaceutically acceptable salt is encompassed by the present invention; especially preferred are the sodium, potassium or lithium salts. Also encompassed are the N-alkylpolyhydroxamine salts, such as N-methyl glucamine, found in PCT publication WO 96/33155. The preferred esters are the ethyl esters. As solid salts, the PUFAs also can be administered in tablet form. For intravenous administration, the PUFAs or derivatives thereof may be incorporated into commercial formulations such as Intralipids. The typical normal adult plasma fatty acid profile comprises 6.64 to 9.46% of ARA, 1.45 to 3.11% of DGLA, and 0.02 to 0.08% of GLA. These PUFAs or their metabolic precursors can be administered, either alone or in mixtures with other PUFAs, to achieve a normal fatty acid profile in a patient. Where desired, the individual components of formulations may be individually provided in kit form, for single or multiple use. A typical dosage of a particular fatty acid is from 0.1 mg to 20 g, or even 100 g daily, and is preferably from 10 mg to 1, 2, 5 or 10 g daily as required, or molar equivalent amounts of derivative forms thereof. Parenteral nutrition compositions comprising from about 2 to about 30 weight percent fatty acids calculated as triglycerides are encompassed by the present invention; preferred is a composition having from about 1 to about 25 weight percent of the total PUFA composition as GLA (USPN 5,196,198). Other vitamins, and particularly fat-soluble vitamins such as vitamin A, D, E and L-carnitine can optionally be included. Where desired, a preservative such as α tocopherol may be added, typically at about 0.1% by weight.

Suitable pharmaceutical compositions may comprise physiologically acceptable sterile aqueous or non-aqueous solutions, dispersions, suspensions or emulsions and sterile powders for reconstitution into sterile injectible solutions or dispersions. Examples of suitable aqueous and non-aqeuous carriers, diluents, solvents or vehicles include water, ethanol, polyols (propylleneglyol, polyethylenegycol, glycerol, and the like), suitable mixtures thereof, vegetable

oils (such as olive oil) and injectable organic esters such as ehyl oleate. Proper fluidity can be maintained, for example, by the maintenance of the required particle size in the case of dispersions and by the use of surfactants. It may also be desirable to include isotonic agents, for example sugars, sodium chloride and the like. Besides such inert diluents, the composition can also include adjuvants, such as wetting agents, emulsifying and suspending agents, sweetening, flavoring and perfuming agents.

Suspensions in addition to the active compounds, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth, or mixtures of these substances and the like.

An especially preferred pharmaceutical composition contains diacetyltartaric acid esters of mono- and diglycerides dissolved in an aqueous medium or solvent. Diacetyltartaric acid esters of mono- and diglycerides have an HLB value of about 9-12 and are significantly more hydrophilic than existing antimicrobial lipids that have HLB values of 2-4. Those existing hydrophobic lipids cannot be formulated into aqueous compositions. As disclosed herein, those lipids can now be solubilized into aqueous media in combination with diacetyltartaric acid esters of mono-and diglycerides. In accordance with this embodiment, diacetyltartaric acid esters of mono- and diglycerides (e.g., DATEM-C12:0) is melted with other active antimicrobial lipids (e.g., 18:2 and 12:0 monoglycerides) and mixed to obtain a homogeneous mixture. Homogeneity allows for increased antimicrobial activity. The mixture can be completely dispersed in water. This is not possible without the addition of diacetyltartaric acid esters of mono- and diglycerides and premixing with other monoglycerides prior to introduction into water. The aqueous composition can then be admixed under sterile conditions with physiologically acceptable diluents, preservatives, buffers or propellants as may be required to form a spray or inhalant.

The present invention also encompasses the treatment of numerous disorders with fatty acids. Supplementation with PUFAs of the present invention can be used to treat restenosis after angioplasty. Symptoms of inflammation, rheumatoid arthritis, and asthma and psoriasis can be treated with the PUFAs of the present invention. Evidence indicates that PUFAs may be involved in calcium metabolism, suggesting that PUFAs of the present invention may be used in the treatment or prevention of osteoporosis and of kidney or urinary tract stones.

The PUFAs of the present invention can be used in the treatment of cancer. Malignant cells have been shown to have altered fatty acid compositions; addition of fatty acids has been shown to slow their growth and cause cell death, and to increase their susceptibility to chemotherapeutic agents. GLA has been shown to cause reexpression on cancer cells of the E-cadherin cellular adhesion molecules, loss of which is associated with aggressive metastasis. Clinical testing of intravenous administration of the water soluble lithium salt of GLA to pancreatic cancer patients produced statistically significant increases in their survival. PUFA supplementation may also be useful for treating cachexia associated with cancer.

The PUFAs of the present invention can also be used to treat diabetes (USPN 4,826,877; Horrobin *et al.*, Am. J. Clin. Nutr. Vol. 57 (Suppl.), 732S-737S). Altered fatty acid metabolism and composition has been demonstrated in diabetic animals. These alterations have been suggested to be involved in some of the long-term complications resulting from diabetes, including retinopathy, neuropathy, nephropathy and reproductive system damage. Primrose oil, which contains GLA, has been shown to prevent and reverse diabetic nerve damage.

The PUFAs of the present invention can be used to treat eczema, reduce blood pressure and improve math scores. Essential fatty acid deficiency has been suggested as being involved in eczema, and studies have shown beneficial effects on eczema from treatment with GLA. GLA has also been shown to reduce increases in blood pressure associated with stress, and to improve

performance on arithmetic tests. GLA and DGLA have been shown to inhibit platelet aggregation, cause vasodilation, lower cholesterol levels and inhibit proliferation of vessel wall smooth muscle and fibrous tissue (Brenner *et al.*, Adv. Exp. Med. Biol. Vol. 83, p. 85-101, 1976). Administration of GLA or DGLA, alone or in combination with EPA, has been shown to reduce or prevent gastro-intestinal bleeding and other side effects caused by non-steroidal anti-inflammatory drugs (USPN 4,666,701). GLA and DGLA have also been shown to prevent or treat endometriosis and premenstrual syndrome (USPN 4,758,592) and to treat myalgic encephalomyelitis and chronic fatigue after viral infections (USPN 5,116,871).

Further uses of the PUFAs of this invention include use in treatment of AIDS, multiple schlerosis, acute respiratory syndrome, hypertension and inflammatory skin disorders. The PUFAs of the inventions also can be used for formulas for general health as well as for geriatric treatments.

Veterinary Applications

It should be noted that the above-described pharmaceutical and nutritional compositions may be utilized in connection with animals, as well as humans, as animals experience many of the same needs and conditions as human. For example, the oil or acids of the present invention may be utilized in animal feed supplements.

The following examples are presented by way of illustration, not of limitation.

Example 1

Isolation of a Δ5-desaturase Nucleotide Sequence from *Mortierella alpina*

Motierella alpina produces arachidonic acid (ARA, 20:4) from the precursor 20:3 by a Δ5-desaturase. A nucleotide sequence encoding the Δ5-desaturase from *Mortierella alpina* was obtained through PCR amplification using *M. alpina* 1st strand cDNA and degenerate oligonucleotide primers corresponding to amino acid sequences conserved between Δ6-desaturases from *Synechocystis* and *Spirulina*. The procedure used was as follows:

Total RNA was isolated from a 3 day old PUFA-producing culture of *Mortierella alpina* using the protocol of Hoge *et al.* (1982) *Experimental Mycology* 6:225-232. The RNA was used to prepare double-stranded cDNA using BRL's lambda-ZipLox system, following the manufacturer's instructions. Several size fractions of the *M. alpina* cDNA were packaged separately to yield libraries with different average-sized inserts. The "full-length" library contains approximately 3 x 10^6 clones with an average insert size of 1.77 kb. The "sequencing-grade" library contains approximately 6 x 10^5 clones with an average insert size of 1.1 kb.

5μg of total RNA was reverse transcribed using BRL Superscript RTase and the primer TSyn (5'-CCAAGCTTCTGCAGGAGCTCTTTTTTT TTTTTTTT-3'), SEQ ID NO:10. Degenerate oligonucleotides were designed to regions conserved between the two cyanobacterial Δ6-desaturase sequences. The specific primers used were D6DESAT-F3 (SEQ ID NO:8) (5'-CUACUACUACUACAYCAYACOTAYACOAAYAT-3') and D6DESAT-R3 (SEQ ID NO:9) (5'-CAUCAUCAUCAUOGGRAAOARRTGRTG-3'), where Y=C+T, R=A+G, and O=I+C. PCR amplification was carried out in a 25μl volume containing: template derived from 40 ng total RNA, 2 pM each primer, 200 μM each deoxyribonucleotide triphosphate, 60 mM Tris-Cl, pH 8.5, 15 mM $(NH_4)_2SO_4$, 2 mM $MgCl_2$. Samples were subjected to an initial denaturation step of 95 degrees (all temperatures Celsius) for 5 minutes, then held at 72 degrees while 0.2 U of Taq polymerase were added. PCR thermocycling conditions were as follows: 94 degrees for 1 min., 45 degrees for 1.5 min., 72 degrees for 2 min. PCR was continued for 35 cycles. PCR using these primers on the *M. alpina* first-strand cDNA produced a 550 bp reaction product. Comparison of the deduced amino acid sequence of the *M. alpina* PCR fragment SEQ ID NO:3 revealed regions of homology with Δ6-desaturases (*see* Figure 5). However, there was only about 28% identity over the region compared.

The PCR product was used as a probe to isolate corresponding cDNA clones from a *M. alpina* library. The longest cDNA clone, Ma29, was designated pCGN5521 and has been completely sequenced on both strands. The cDNA is contained as a 1481 bp insert in the vector pZL1 (Bethesda Research Laboratories) and, beginning with the first ATG, contains an open reading frame encoding 446 amino acids. The reading frame contains the sequence deduced from the PCR fragment. The sequence of the cDNA insert was found to contain regions of homology to Δ6-desaturases (*see* Figure 5). For example, three conserved "histidine boxes" (that have been observed in membrane-bound desaturases (Okuley *et al.*, (1994) *The Plant Cell* 6:147-158)) were found to be present in the *Mortierella* sequence at amino acid positions

171-175, 207-212, and 387-391 (*see* Figure 3). However, the typical "HXXHH" amino acid motif for the third histidine box for the *Mortierella* desaturase was found to be QXXHH, SEQ ID NO:11-12. Surprisingly, the amino-terminus of the encoded protein, showed significant homology to cytochrome b5 proteins. Thus, the *Mortierella* cDNA clone appears to represent a fusion between a cytochrome b5 and a fatty acid desaturase. Since cytochrome b5 is believed to function as the electron donor for membrane-bound desaturase enzymes, it is possible that the N-terminal cytochrome b5 domain of this desaturase protein is involved in its function. This may be advantageous when expressing the desaturase in heterologous systems for PUFA production.

Example 2

Expression of *M. alpina* Desaturase Clones in Baker's Yeast

Yeast Transformation

Lithium acetate transformation of yeast was performed according to standard protocols (*Methods in Enzymology*, Vol. 194, p. 186-187, 1991). Briefly, yeast were grown in YPD at 30°C. Cells were spun down, resuspended in TE, spun down again, resuspended in TE containing 100 mM lithium acetate, spun down again, and resuspended in TE/lithium acetate. The resuspended yeast were incubated at 30°C for 60 minutes with shaking. Carrier DNA was added, and the yeast were aliquoted into tubes. Transforming DNA was added, and the tubes were incubated for 30 min. at 30°C. PEG solution (35% (w/v) PEG 4000, 100 mM lithium acetate, TE pH7.5) was added followed by a 50 min. incubation at 30°C. A 5 min. heat shock at 42°C was performed, the cells were pelleted, washed with TE, pelleted again and resuspended in TE. The resuspended cells were then plated on selective media.

Desaturase Expression in Transformed Yeast

The cDNA clones from *Mortierella alpina* were screened for desaturase activity in baker's yeast. A canola Δ15-desaturase (obtained by PCR using 1st

strand cDNA from *Brassica napus* cultivar 212/86 seeds using primers based on the published sequence (Arondel *et al. Science* 258:1353-1355)) was used as a positive control. The Δ15-desaturase gene and the gene from cDNA clone Ma29 was inserted into the expression vector pYES2 (Invitrogen), resulting in plasmids pCGR-2 and pCGR-4, respectively. These plasmids were transfected into *S. cerevisiae* yeast strain 334 and expressed after induction with galactose and in the presence of substrates that allowed detection of specific desaturase activity. The control strain was *S. cerevisiae* strain 334 containing the unaltered pYES2 vector. The substrates used, the products produced and the indicated desaturase activity were: DGLA (conversion to ARA would indicate Δ5-desaturase activity), linolenic acid (conversion to GLA would indicate Δ6-desaturase activity; conversion to ALA would indicate Δ15-desaturase activity), oleic acid (an endogenous substrate made by *S. cerevisiae*, conversion to linolenic acid would indicate Δ12-desaturase activity, which *S. cerevisiae* lacks), or ARA (conversion to EPA would indicate Δ17-desaturase activity). The results are provided in Table 1 below. The lipid fractions were extracted as follows: Cultures were grown for 48-52 hours at 15°C. Cells were pelleted by centrifugation, washed once with sterile ddH_20, and repelleted. Pellets were vortexed with methanol; chloroform was added along with tritridecanoin (as an internal standard). The mixtures were incubated for at least one hour at room temperature or at 4°C overnight. The chloroform layer was extracted and filtered through a Whatman filter with one gram of anhydrous sodium sulfate to remove particulates and residual water. The organic solvents were evaporated at 40°C under a stream of nitrogen. The extracted lipids were then derivatized to fatty acid methyl esters (FAME) for gas chromatography analysis (GC) by adding 2 ml of 0.5 N potassium hydroxide in methanol to a closed tube. The samples were heated to 95°C to 100°C for 30 minutes and cooled to room temperature. Approximately 2 ml of 14 % boron trifluoride in methanol was added and the heating repeated. After the extracted lipid mixture cooled, 2 ml of water and 1 ml of hexane were added to extract the FAME for analysis by GC. The percent conversion was calculated by dividing the product produced

by the sum of (the product produced and the substrate added) and then multiplying by 100. To calculate the oleic acid percent conversion, as no substrate was added, the total linolenic acid produced was divided by the sum of (oleic acid and linolenic acid produced), then multiplying by 100.

Table 1

M. alpina Desaturase Expression in Baker's Yeast

CLONE	TYPE OF ENZYME ACTIVITY	% CONVERSION OF SUBSTRATE
pCGR-2	Δ6	0 (18:2 to 18:3ω6)
(canola Δ15	Δ15	16.3 (18:2 to 18:3ω3)
desaturase)	Δ5	2.0 (20:3 to 20:4ω6)
	Δ17	2.8 (20:4 to 20:5ω3)
	Δ12	1.8 (18:1 to 18:2ω6)
pCGR-4	Δ6	0
(*M. alpina*	Δ15	0
Ma29)	Δ5	15.3
	Δ17	0.3
	Δ12	3.3

The Δ15-desaturase control clone exhibited 16.3% conversion of the substrate. The pCGR-4 clone expressing the Ma29 cDNA converted 15.3% of the 20:3 substrate to 20:4ω6, indicating that the gene encodes a Δ5-desaturase. The background (non-specific conversion of substrate) was between 0-3% in these cases. We also found substrate inhibition of the activity by using different concentrations of the substrate. When substrate was added to 100 μM, the percent conversion to product dropped compared to when substrate was added to 25 μM (see below). Additionally, by varying the DGLA substrate concentrations, between about 5 μM to about 200 μM percent conversion of DGLA to ARA ranged from about 5% to 75% with the *M. alpina* Δ5-desaturase.

These data show that desaturases with different substrate specificities can be expressed in a heterologous system and used to produce poly-unsaturated long chain fatty acids.

Table 2 represents fatty acids of interest as a percent of the total lipid extracted from the yeast host *S. cerevisiae* 334 with the indicated plasmid. No glucose was present in the growth media. Affinity gas chromatography was used to separate the respective lipids. GC/MS was employed to verify the identity product(s). The expected product for the *B. napus* Δ15-desaturase, α-linolenic acid, was detected when its substrate, linolenic acid, was added exogenously to the induced yeast culture. This finding demonstrates that yeast expression of a desaturase gene can produce functional enzyme and detectable amounts of product under the current growth conditions. Both exogenously added substrates were taken up by yeast, although slightly less of the longer chain PUFA, dihomo-γ-linolenic acid (20:3), was incorporated into yeast than linolenic acid (18:2) when either was added in free form to the induced yeast cultures. Arachidonic acid was detected as a novel PUFA in yeast when dihomo-γ-linolenic acid was added as the substrate to *S. cerevisiae* 334 (pCGR-4). This identifies pCGR-4 (MA29) as the Δ5-desaturase from *M. alpina*. Prior to this, no isolation and expression of a Δ5-desaturase from any source has been reported.

Table 2

Fatty Acid as a Percentage of Total Lipid Extracted from Yeast

Plasmid in Yeast (enzyme)	18:2 Incorporated	α-18:3 Produced	γ-18:3 Produced	20:3 Incorporated	20:4 Produced	18:1* Present	18:2 Produced

Example 3
Optimization of Culture Conditions

Table 3A shows the effect of exogenous free fatty acid substrate concentration on yeast uptake and conversion to fatty acid product as a percentage of the total yeast lipid extracted. In all instances, low amounts of exogenous substrate (1-10 μM) resulted in low fatty acid substrate uptake and product formation. Between 25 and 50 μM concentration of free fatty acid in the growth and induction media gave the highest percentage of fatty acid product formed, while the 100 μM concentration and subsequent high uptake into yeast appeared to decrease or inhibit the desaturase activity. The feedback inhibition of high fatty acid substrate concentration was well illustrated when the percent conversion rates of the respective fatty acid substrates to their respective products were compared in Table 3B. In all cases, 100 μM substrate concentration in the growth media decreased the percent conversion to product. The effect of media composition was also evident when glucose was present in the growth media for the Δ5-desaturase, since the percent of substrate uptake was decreased at 25 μM (Table 3A). However, the percent conversion by Δ5-desaturase increased by 18% and the percent product formed remained the same in the presence of glucose in the growth media.

Table 4 shows the amount of fatty acid produced by a recombinant desaturase from induced yeast cultures when different amounts of free fatty acid substrate were used. Fatty acid weight was determined since the total amount of lipid varied dramatically when the growth conditions were changed, such as the presence of glucose in the yeast growth and induction media. To better

determine the conditions when the recombinant desaturase would produce the most PUFA product, the quantity of individual fatty acids were examined. The absence of glucose reduced the amount of arachidonic acid produced by Δ5-desaturase by half. For Δ5-desaturase the amount of total yeast lipid was decreased by almost half in the absence of glucose.

Example 4

Distribution of PUFAs in Yeast Lipid Fractions

Table 5 illustrates the uptake of free fatty acids and their new products formed in yeast lipids as distributed in the major lipid fractions. A total lipid extract was prepared as described above. The lipid extract was separated on TLC plates, and the fractions were identified by comparison to standards. The bands were collected by scraping, and internal standards were added. The fractions were then saponified and methylated as above, and subjected to gas chromatography. The gas chromatograph calculated the amount of fatty acid by comparison to a standard. It would appear that the substrates are accessible in the phospholipid form to the desaturases.

Table 5

SC = *S. cerevisiae* (plasmid)

Example 5
Further Culture Optimization

The growth and induction conditions for optimal activities of desaturases in *Saccharomyces cerevisiae* were evaluated. Various culture conditions that were manipulated for optimal activity were: I) induction temperature, ii) concentration of inducer, iii) timing of substrate addition, iv) concentration of substance, v) sugar source, vi) growth phase at induction. These studies were done using Δ5-desaturase gene from *Mortierella alpina* (MA 29). In addition, the effect of changing host strain on expression of the Δ5-desaturase gene was also determined.

As described above, the best rate of conversion of substrate to ARA was observed at a substrate concentration of 1 μM, however, the percentage of ARA in the total fatty acids was highest at 25 μM substrate concentration. To determine if the substrate needed to be modified to a readily available form before it could be utilized by the desaturase, the substrate was added either 15 hours before induction or concomitant with inducer addition (indicated as after, in Figure 6A). As it can be seen in Figure 6A, addition of substrate before induction did not have a significant effect on the activity of Δ5-desaturase. In fact, addition of substrate along with the inducer was slightly better for expression/activity of Δ5-desaturase, as ARA levels in the total fatty acids were

higher. However, the rate of conversion of substrate to product was slightly lower.

The effect of inducer concentration of expression/activity of *Mortierella* Δ5-desaturase was examined by inducing SC334/pCGR5 with 0.5 or 2% (w/v) of galactose. As shown in Figures 7A and 7B, expression of Δ5-desaturase was higher when induced with 0.5% galactose. Furthermore, rate of conversion of substrate to product was also better when SC334/pCGR5 was induced with 0.5% galactose vs 2% galactose.

To determine the effect of temperature on Δ5-desaturase activity, the SC334 host strain, transformed with pCGR5 (SC334/pCGR5) was grown and induced at 15° C, 25°C, 30°C and 37°C. The quantity of ARA (20:4n6) produced in SC334/pCGR5 cultures, supplemental with substrate 20:3n6, was measured by fatty acid analysis. Figure 8A depicts the quantity of 20:3n6 and 20:4n6, expressed as percentage of total fatty acids. Figure 8B depicts the rate of conversion of substrate to product. Growth and induction of SC334/pCGR5 at 25°C, was the best for the expression of Δ5-desaturase as evidenced by the highest levels of arachidonic acid in the total fatty acids. Additionally the highest rate of conversion of substrate to product also occurred at 25°C. Growth and induction at 15°C gave the lowest expression of ARA, whereas at 37°C gave the lowest conversion of substrate to product.

The effect of yeast strain on expression of the Δ5-desaturase gene was studied in 5 different host strains; INVSC1, INVSC2, YTC34, YTC41, and SC334, at 15°C and 30°C. At 15°C, SC334 has the highest percentage of ARA in total fatty acids, suggesting higher activity of Δ5-desaturase in SC334. The rate of conversion of substrate to product, however is lowest in SC334 and highest in INVSC1 (Fig. 9A and B). At 30°C, the highest percentage of product (ARA) in total fatty acids was observed in INVSC2, although the rate of conversion of substrate to product in INVSC2 was slightly lower than INVSC1 (Fig. 10A and B).

ARA, the product of Δ5-desaturase, is stored in the phospholipid faction (Example 4). Therefore the quantity of ARA produced in yeast is limited by the amount that can be stored in the phospholipid fraction. If ARA could also be stored in other fractions such as the triglyceride fraction, the quantity of ARA produced in yeast might be increased. To test this hypothesis, the Δ5-desaturase gene was expressed in the yeast host strain DBY746 (obtained from the Yeast Genetic Stock Centre, 1021 Donner Laboratory, Berkeley, CA 94720. The genotype of strain DBY746 is Matα, his3-Δ1, leu2-3, leu2-112, ura3-32, trp1-289, gal). The DBY746 yeast strain has an endogenous gene for choline transferase. The presence of this enzyme might enable the DBY746 strain to convert excess phospholipids into triglycerides fraction. Results in Fig. 11 show no increase in the conversion of substrate to product as compared to SC334, which does not have the gene for choline transferase.

To study the effect of media on expression of Δ5-desaturase, pCGR4/SC334 was grown in four different media at two different temperatures (15°C and 30°) and in two different host strains (SC334 and INVSC1). The composition of the media was as follows:

Media A: mm-Ura, + 2% galactose + 2% glucose.

Media B: mm-Ura, + 20% galactose + 2% Glucose + 1M sorbitol (pH5.8)

Media C: mm-Ura, + 2% galactose + 2% raffinose

Media D: mm-Ura, + 2% galactose +2% raffinose + 1M sorbitol (pH5.8)

mm=minimal media

Results show that the highest conversion rate of substrate to product at 15°C in SC334 was observed in media A. The highest conversion rate overall for Δ5-desaturase in SC334 was at 30° in media D. The highest conversion rate of Δ5-desaturase in INVSC1 was also at 30° in media D (Figures 12A and 12B).

These data show that a DNA encoding a desaturase that can convert DGLA to ARA can be isolated from *Mortierella alpina* and can be expressed in a heterologous system and used to produce poly-unsaturated long chain fatty

acids. Exemplified is the production of ARA from the precursor DGLA by expression of a Δ5-desaturase in yeast.

Example 6

Identification of Homologues to *M. alpina* Δ5 and Δ6 desaturases

A nucleic acid sequence that encodes a putative Δ5 desaturase was identified through a TBLASTN search of the est databases through NCBI using amino acids 100-446 of Ma29 as a query. The truncated portion of the Ma29 sequence was used to avoid picking up homologies based on the cytochrome b5 portion at the N-terminus of the desaturase. The deduced amino acid sequence of an est from *Dictyostelium discoideum* (accession # C25549) shows very significant homology to Ma29 and lesser, but still significant homology to Ma524. The DNA sequence is presented as SEQ ID NO:13. The amino acid sequence is presented as SEQ ID NO:14.

Example 7

Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms

To look for desaturases involved in PUFA production, a cDNA library was constructed from total RNA isolated from Phaeodactylum tricornutum. A plasmid-based cDNA library was constructed in pSPORT1 (GIBCO-BRL) following manufacturer's instructions using a commercially available kit (GIBCO-BRL). Random cDNA clones were sequenced and nucleic acid sequences that encode putative Δ5 or Δ6 desaturases were identified through BLAST search of the databases and comparison to Ma29 and Ma524 sequences.

One clone was identified from the *Phaeodactylum* library with homology to Ma29 and Ma524; it is called 144-011-B12. The DNA sequence is presented as SEQ ID NO:15. The amino acid sequence is presented as SEQ ID NO:16.

Example 8

Identification of *M. alpina* Δ5 and Δ6 homologues in other PUFA-producing organisms

To look for desaturases involved in PUFA production, a cDNA library was constructed from total RNA isolated from *Schizochytrium* species. A plasmid-based cDNA library was constructed in pSPORT1 (GIBCO-BRL) following manufacturer's instructions using a commercially available kit (GIBCO-BRL). Random cDNA clones were sequenced and nucleic acid sequences that encode putative Δ5 or Δ6 desaturases were identified through BLAST search of the databases and comparison to Ma29 and Ma524 sequences.

One clone was identified from the *Schizochytrium* library with homology to Ma29 and Ma524; it is called 81-23-C7. This clone contains a ~1 kb insert. Partial sequence was obtained from each end of the clone using the universal forward and reverse sequencing primers. The DNA sequence from the forward primer is presented as SEQ ID NO:17. The peptide sequence is presented as SEQ ID NO:18. The DNA sequence from the reverse primer is presented as SEQ ID NO:19. The amino acid sequence from the reverse primer is presented as SEQ ID NO:20.

Example 9

Human Desaturase Gene Sequences

Human desaturase gene sequences potentially involved in long chain polyunsaturated fatty acid biosynthesis were isolated based on homology between the human cDNA sequences and *Mortierella alpina* desaturase gene sequences. The three conserved "histidine boxes" known to be conserved among membrane-bound desaturases were found. As with some other membrane-bound desaturases the final HXXHH histidine box motif was found to be QXXHH. The amino acid sequence of the putative human desaturases exhibited homology to *M. alpina* Δ5, Δ6, Δ9, and Δ12 desaturases.

The *M. alpina* Δ5 desaturase and Δ6 desaturase cDNA sequences were used to search the LifeSeq database of Incyte Pharmaceuticals, Inc., Palo Alto, California 94304. The Δ5 desaturase sequence was divided into fragments; 1) amino acid no. 1-150, 2) amino acid no. 151-300, and 3) amino acid no. 301-446. The Δ6 desaturase sequence was divided into three fragments; 1) amino acid no. 1-150, 2) amino acid no. 151-300, and 3) amino acid no. 301-457. These polypeptide fragments were searched against the database using the "tblastn" algorithm. This alogarithm compares a protein query sequence against a nucleotide sequence database dynamically translated in all six reading frames (both strands).

The polypeptide fragments 2 and 3 of *M. alpina* Δ5 and Δ6 have homologies with the CloneID sequences as outlined in Table 6. The CloneID represents an individual sequence from the Incyte LifeSeq database. After the "tblastn" results have been reviewed, Clone Information was searched with the default settings of Stringency of >=50, and Productscore <=100 for different CloneID numbers. The Clone Information Results displayed the information including the ClusterID, CloneID, Library, HitID, Hit Description. When selected, the ClusterID number displayed the clone information of all the clones that belong in that ClusterID. The Assemble command assembles all of the CloneID which comprise the ClusterID. The following default settings were used for GCG (Genetics Computer Group, University of Wisconsin Biotechnology Center, Madison, Wisconsin 53705) Assembly:

Word Size:	7
Minimum Overlap:	14
Stringency:	0.8
Minimum Identity:	14
Maximum Gap:	10
Gap Weight:	8
Length Weight:	2

GCG Assembly Results displayed the contigs generated on the basis of sequence information within the CloneID. A contig is an alignment of DNA sequences based on areas of homology among these sequences. A new sequence (consensus sequence) was generated based on the aligned DNA sequences within a contig. The contig containing the CloneID was identified, and the ambiguous sites of the consensus sequence was edited based on the alignment of the CloneIDs (see SEQ ID NO:21 - SEQ ID NO:25) to generate the best possible sequence. The procedure was repeated for all six CloneID listed in Table 6. This produced five unique contigs. The edited consensus sequences of the 5 contigs were imported into the Sequencher software program (Gene Codes Corporation, Ann Arbor, Michigan 48 105). These consensus sequences were assembled. The contig 2511785 overlaps with contig 3506132, and this new contig was called 2535 (SEQ ID NO:27). The contigs from the Sequencher program were copied into the Sequence Analysis software package of GCG.

Each contig was translated in all six reading frames into protein sequences. The *M. alpina* Δ5 (MA29) and Δ6 (MA524) sequences were compared with each of the translated contigs using the FastA search (a Pearson and Lipman search for similarity between a query sequence and a group of sequences of the same type (nucleic acid or protein)). Homology among these sequences suggest the open reading frames of each contig. The homology among the *M. alpina* Δ5 and Δ6 to contigs 2535 and 3854933 were utilized to create the final contig called 253538a. Figure 13 is the FastA match of the final contig 253538a and MA29, and Figure 14 is the FastA match of the final contig 253538a and MA524. The DNA sequences for the various contigs are presented in SEQ ID NO:21 -SEQ ID NO:27. The various peptide sequences are shown in SEQ ID NO:28 - SEQ ID NO:34.

Although the open reading frame was generated by merging the two contigs, the contig 2535 shows that there is a unique sequence in the beginning of this contig which does not match with the contig 3854933. Therefore, it is

possible that these contigs were generated from independent desaturase like human genes.

The contig 253538a contains an open reading frame encoding 432 amino acids. It starts with Gln (CAG) and ends with the stop codon (TGA). The contig 253538a aligns with both *M. alpina* Δ5 and Δ6 sequences, suggesting that it could be either of the desaturases, as well as other known desaturases which share homology with each other. The individual contigs listed in Table 6, as well as the intermediate contig 2535 and the final contig 253538a can be utilized to isolate the complete genes for human desaturases.

Uses of the human desaturases

These human sequences can be expressed in yeast and plants utilizing the procedures described in the preceding examples. For expression in mammalian cells and transgenic animals, these genes may provide superior codon bias. These human sequences can also be used to identify related desaturase sequences.

Table 6

Sections of the Desaturases	Clone ID from LifeSeq Database	Keyword
151-300 Δ5	3808675	Fatty acid desaturase
301-446 Δ5	354535	Δ6
151-300 Δ6	3448789	Δ6
151-300 Δ6	1362863	Δ6
151-300 Δ6	2394760	Δ6
301-457 Δ6	3350263	Δ6

Example 10

Nutritional Compositions

The PUFAs of the previous examples can be utilized in various nutritional supplements, infant formulations, nutritional substitutes and other nutrition solutions.

I. INFANT FORMULATIONS

A. Is mil® S y Formula with Iron.

Usage: As a beverage for infants, children and adults with an allergy or sensitivity to cow's milk. A feeding for patients with disorders for which lactose should be avoided: lactase deficiency, lactose intolerance and galactosemia.

Features:

- Soy protein isolate to avoid symptoms of cow's-milk-protein allergy or sensitivity
- Lactose-free formulation to avoid lactose-associated diarrhea
- Low osmolaity (240 mOsm/kg water) to reduce risk of osmotic diarrhea.
- Dual carbohydrates (corn syrup and sucrose) designed to enhance carbohydrate absorption and reduce the risk of exceeding the absorptive capacity of the damaged gut.
- 1.8 mg of Iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.
- Recommended levels of vitamins and minerals.
- Vegetable oils to provide recommended levels of essential fatty acids.
- Milk-white color, milk-like consistency and pleasant aroma.

Ingredients: (Pareve, ®) 85% water, 4.9% corn syrup, 2.6% sugar (sucrose), 2.1% soy oil, 1.9% soy protein isolate, 1.4% coconut oil, 0.15% calcium citrate, 0.11 % calcium phosphate tribasic, potassium citrate, potassium phosphate monobasic, potassium chloride, mono- and disglycerides, soy lecithin, carrageenan, ascorbic acid, L-methionine, magnesium chloride, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic

acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

B. Isomil® DF Soy Formula For Diarrhea.

Usage: As a short-term feeding for the dietary management of diarrhea in infants and toddlers.

Features:

- First infant formula to contain added dietary fiber from soy fiber specifically for diarrhea management.
- Clinically shown to reduce the duration of loose, watery stools during mild to severe diarrhea in infants.
- Nutritionally complete to meet the nutritional needs of the infant.
- Soy protein isolate with added L-methionine meets or exceeds an infant's requirement for all essential amino acids.
- Lactose-free formulation to avoid lactose-associated diarrhea.
- Low osmolality (240 mOsm/kg water) to reduce the risk of osmotic diarrhea.
- Dual carbohydrates (corn syrup and sucrose) designed to enhance carbohydrate absorption and reduce the risk of exceeding the absorptive capacity of the damaged gut.
- Meets or exceeds the vitamin and mineral levels recommended by the Committee on Nutrition of the American Academy of Pediatrics and required by the Infant Formula Act.
- 1.8 mg of iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.
- Vegetable oils to provide recommended levels of essential fatty acids.

Ingredients: (Pareve, ®) 86% water, 4.8% corn syrup, 2.5% sugar (sucrose), 2.1% soy oil, 2.0% soy protein isolate, 1.4% coconut oil, 0.77% soy

fiber, 0.12% calcium citrate, 0.11 % calcium phosphate tribasic, 0.10% potassium citrate, potassium chloride, potassium phosphate monobasic, mono- and disglycerides, soy lecithin, carrageenan, magnesium chloride, ascorbic acid, L-methionine, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

C. Isomil® SF Sucrose-Free Soy Formula With Iron.

Usage: As a beverage for infants, children and adults with an allergy or sensitivity to cow's-milk protein or an intolerance to sucrose. A feeding for patients with disorders for which lactose and sucrose should be avoided.

Features:

- Soy protein isolate to avoid symptoms of cow's-milk-protein allergy or sensitivity.
- Lactose-free formulation to avoid lactose-associated diarrhea (carbohydrate source is Polycose® Glucose Polymers).
- Sucrose free for the patient who cannot tolerate sucrose.
- Low osmolality (180 mOsm/kg water) to reduce risk of osmotic diarrhea.
- 1.8 mg of iron (as ferrous sulfate) per 100 Calories to help prevent iron deficiency.
- Recommended levels of vitamins and minerals.
- Vegetable oils to provide recommended levels of essential fatty acids.
- Milk-white color, milk-like consistency and pleasant aroma.

Ingredients: (Pareve, ®) 75% water, 11.8% hydrolized cornstarch, 4.1% soy oil, 4.1% soy protein isolate, 2.8% coconut oil, 1.0% modified cornstarch,

0.38% calcium phosphate tribasic, 0.17% potassium citrate, 0.13% potassium chloride, mono- and disglycerides, soy lecithin, magnesium chloride, abscorbic acid, L-methionine, calcium carbonate, sodium chloride, choline chloride, carrageenan, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

D. Isomil® 20 Soy Formula With Iron Ready To Feed, 20 Cal/fl oz.

Usage: When a soy feeding is desired.

Ingredients: (Pareve, ®) 85% water, 4.9% corn syrup, 2.6% sugar (sucrose), 2.1% soy oil, 1.9% soy protein isolate, 1.4% coconut oil, 0.15% calcium citrate, 0.11% calcium phosphate tribasic, potassium citrate, potassium phosphate monobasic, potassium chloride, mono- and disglycerides, soy lecithin, carrageenan, abscorbic acid, L-methionine, magnesium chloride, potassium phosphate dibasic, sodium chloride, choline chloride, taurine, ferrous sulfate, m-inositol, alpha-tocopheryl acetate, zinc sulfate, L-carnitine, niacinamide, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, potassium iodide, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

E. Similac® Infant Formula

Usage: When an infant formula is needed: if the decision is made to discontinue breastfeeding before age 1 year, if a supplement to breastfeeding is needed or as a routine feeding if breastfeeding is not adopted.

Features:

- Protein of appropriate quality and quantity for good growth; heat-denatured, which reduces the risk of milk-associated enteric blood loss.

- Fat from a blend of vegetable oils (doubly homogenized), providing essential linoleic acid that is easily absorbed.
- Carbohydrate as lactose in proportion similar to that of human milk.
- Low renal solute load to minimize stress on developing organs.
- Powder, Concentrated Liquid and Ready To Feed forms.

Ingredients: (®-D) Water, nonfat milk, lactose, soy oil, coconut oil, mono- and diglycerides, soy lecithin, abscorbic acid, carrageenan, choline chloride, taurine, m-inositol, alpha-tocopheryl acetate, zinc sulfate, niacinamid, ferrous sulfate, calcium pantothenate, cupric sulfate, vitamin A palmitate, thiamine chloride hydrochloride, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

F. Similac® NeoCare Premature Infant Formula With Iron

Usage: For premature infants' special nutritional needs after hospital discharge. Similac NeoCare is a nutritionally complete formula developed to provide premature infants with extra calories, protein, vitamins and minerals needed to promote catch-up growth and support development.

Features:

- Reduces the need for caloric and vitamin supplementation. More calories (22 Cal/fl oz) then standard term formulas (20 Cal/fl oz).
- Highly absorbed fat blend, with medium-chain triglycerides (MCT oil) to help meet the special digestive needs of premature infants.
- Higher levels of protein, vitamins and minerals per 100 Calories to extend the nutritional support initiated in-hospital.
- More calcium and phosphorus for improved bone mineralization.

Ingredients: ®-D Corn syrup solids, nonfat milk, lactose, whey protein concentrate, soy oil, high-oleic safflower oil, fractionated coconut oil (medium-chain triglycerides), coconut oil, potassium citrate, calcium phosphate tribasic, calcium carbonate, ascorbic acid, magnesium chloride, potassium chloride,

sodium chloride, taurine, ferrous sulfate, m-inositol, choline chloride, ascorbyl palmitate, L-carnitine, alpha-tocopheryl acetate, zinc sulfate, niacinamide, mixed tocopherols, sodium citrate, calcium pantothenate, cupric sulfate, thiamine chloride hydrochloride, vitamin A palmitate, beta carotene, riboflavin, pyridoxine hydrochloride, folic acid, manganese sulfate, phylloquinone, biotin, sodium selenite, vitamin D_3 and cyanocobalamin.

G. Similac Natural Care Low-Iron Human Milk Fortifier Ready To Use, 24 Cal/fl oz.

Usage: Designed to be mixed with human milk or to be fed alternatively with human milk to low-birth-weight infants.

Ingredients: ®-D Water, nonfat milk, hydrolyzed cornstarch, lactose, fractionated coconut oil (medium-chain triglycerides), whey protein concentrate, soil oil, coconut oil, calcium phosphate tribasic, potassium citrate, magnesium chloride, sodium citrate, ascorbic acid, calcium carbonate, mono- and diglycerides, soy lecithin, carrageenan, choline chloride, m-inositol, taurine, niacinamide, L-carnitine, alpha tocopheryl acetate, zinc sulfate, potassium chloride, calcium pantothenate, ferrous sulfate, cupric sulfate, riboflavin, vitamin A palmitate, thiamine chloride hydrochloride, pyridoxine hydrochloride, biotin, folic acid, manganese sulfate, phylloquinone, vitamin D_3, sodium selenite and cyanocobalamin.

Various PUFAs of this invention can be substituted and/or added to the infant formulae described above and to other infant formulae known to those in the art..

II. NUTRITIONAL FORMULATIONS

A. ENSURE®

Usage: ENSURE is a low-residue liquid food designed primarily as an oral nutritional supplement to be used with or between meals or, in appropriate amounts, as a meal replacement. ENSURE is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets. Although it is primarily an oral supplement, it can be fed by tube.

Patient C nditi ns:

- For patients on modified diets
- For elderly patients at nutrition risk
- For patients with involuntary weight loss
- For patients recovering from illness or surgery
- For patients who need a low-residue diet

Ingredients:

®-D Water, Sugar (Sucrose), Maltodextrin (Corn), Calcium and Sodium Caseinates, High-Oleic Safflower Oil, Soy Protein Isolate, Soy Oil, Canola Oil, Potassium Citrate, Calcium Phosphate Tribasic, Sodium Citrate, Magnesium Chloride, Magnesium Phosphate Dibasic, Artificial Flavor, Sodium Chloride, Soy Lecithin, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Gellan Gum, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Folic Acid, Sodium Molybdate, Chromium Chloride, Biotin, Potassium Iodide, Sodium Selenate.

B. ENSURE® BARS

Usage: ENSURE BARS are complete, balanced nutrition for supplemental use between or with meals. They provide a delicious, nutrient-rich alternative to other snacks. ENSURE BARS contain <1 g lactose/bar, and Chocolate Fudge Brownie flavor is gluten-free. (Honey Graham Crunch flavor contains gluten.)

Patient Conditions:

- For patients who need extra calories, protein, vitamins and minerals
- Especially useful for people who do not take in enough calories and nutrients

- For people who have the ability to chew and swallow
- Not to be used by anyone with a peanut allergy or any type of allergy to nuts.

Ingredients:

Honey Graham Crunch -- High-Fructose Corn Syrup, Soy Protein Isolate, Brown Sugar, Honey, Maltodextrin (Corn), Crisp Rice (Milled Rice, Sugar [Sucrose], Salt [Sodium Chloride] and Malt), Oat Bran, Partially Hydrogenated Cottonseed and Soy Oils, Soy Polysaccharide, Glycerine, Whey Protein Concentrate, Polydextrose, Fructose, Calcium Caseinate, Cocoa Powder, Artificial Flafors, Canola Oil, High-Oleic Safflower Oil, Nonfat Dry Milk, Whey Powder, Soy Lecithin and Corn Oil. Manufactured in a facility that processes nuts.

Vitamins and Minerals:

Calcium Phosphate Tribasic, Potassium Phosphate Dibasic, Magnesium Oxide, Salt (Sodium Chloride), Potassium Chloride, Ascorbic Acid, Ferric Orthophosphate, Alpha-Tocopheryl Acetate, Niacinamide, Zinc Oxide, Calcium Pantothenate, Copper Gluconate, Manganese Sulfate, Riboflavin, Beta-Carotene, Pyridoxine Hydrochloride, Thiamine Mononitrate, Folic Acid, Biotin, Chromium Chloride, Potassium Iodide, Sodium Selenate, Sodium Molybdate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein:

Honey Graham Crunch - The protein source is a blend of soy protein isolate and milk proteins.

Soy protein isolate	74%
Milk proteins	26%

Fat:

Honey Graham Crunch - The fat source is a blend of partially hydrogenated cottonseed and soybean, canola, high oleic safflower, and corn oils, and soy lecithin.

Partially hydrogenated cottonseed and soybean oil	76%
Canola oil	8%
High-oleic safflower oil	8%
Corn oil	4%
Soy lecithin	4%

Carbohydrate:

Honey Graham Crunch - The carbohydrate source is a combination of high-fructose corn syrup, brown sugar, maltodextrin, honey, crisp rice, glycerine, soy polysaccharide, and oat bran.

High-fructose corn syrup	24%
Brown sugar	21%
Maltodextrin	12%
Honey	11%
Crisp rice	9%
Glycerine	9%
Soy polysaccharide	7%
Oat bran	7%\

C. ENSURE® HIGH PROTEIN

Usage: ENSURE HIGH PROTEIN is a concentrated, high-protein liquid food designed for people who require additional calories, protein, vitamins, and minerals in their diets. It can be used as an oral nutritional supplement with or between meals or, in appropriate amounts, as a meal replacement. ENSURE HIGH PROTEIN is lactose- and gluten-free, and is suitable for use by people recovering from general surgery or hip fractures and by patients at risk for pressure ulcers.

Patient Conditions

- For patients who require additional calories, protein, vitamins, and minerals, such as patients recovering from general surgery or hip fractures, patients at risk for pressure ulcers, and patients on low-cholesterol diets

Features-

- Low in saturated fat
- Contains 6 g of total fat and < 5 mg of cholesterol per serving
- Rich, creamy taste
- Excellent source of protein, calcium, and other essential vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients:

Vanilla Supreme: -®-D Water, Sugar (Sucrose), Maltodextrin (Corn), Calcium and Sodium Caseinates, High-Oleic Safflower Oil, Soy Protein Isolate, Soy Oil, Canola Oil, Potassium Citrate, Calcium Phosphate Tribasic, Sodium Citrate, Magnesium Chloride, Magnesium Phosphate Dibasic, Artificial Flavor, Sodium Chloride, Soy Lecithin, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Suffate, Alpha-Tocopheryl Acetate, Gellan Gum, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Folio Acid, Sodium Motybdate, Chromium Chloride, Biotin, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D.3 and Cyanocobalamin.

Protein:

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	85%
Soy protein isolate	15%

Fat:

The fat source is a blend of three oils: high-oleic safflower, canola, and soy.

High-oleic safflower oil	40%

Canola oil	30%
Soy oil	30%

The level of fat in ENSURE HIGH PROTEIN meets American Heart Association (AHA) guidelines. The 6 grams of fat in ENSURE HIGH PROTEIN represent 24% of the total calories, with 2.6% of the fat being from saturated fatty acids and 7.9% from polyunsaturated fatty acids. These values are within the AHA guidelines of $\leq$ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and $\leq$ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate:

ENSURE HIGH PROTEIN contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla supreme, chocolate royal, wild berry, and banana), plus VARI-FLAVORSO® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Sucrose	60%
Maltodextrin	40%

Chocolate

Sucrose	70%
Maltodextrin	30%

D. ENSURE ® LIGHT

Usage: ENSURE LIGHT is a low-fat liquid food designed for use as an oral nutritional supplement with or between meals. ENSURE LIGHT is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions:

- For normal-weight or overweight patients who need extra nutrition in a supplement that contains 50% less fat and 20% fewer calories than ENSURE
- For healthy adults who don't eat right and need extra nutrition

Features:

- Low in fat and saturated fat
- Contains 3 g of total fat per serving and < 5 mg cholesterol
- Rich, creamy taste
- Excellent source of calcium and other essential vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients:

French Vanilla: ®-D Water, Maltodextrin (Corn), Sugar (Sucrose), Calcium Caseinate, High-Oleic Safflower Oil, Canola Oil, Magnesium Chloride, Sodium Citrate, Potassium Citrate, Potassium Phosphate Dibasic, Magnesium Phosphate Dibasic, Natural and Artificial Flavor, Calcium Phosphate Tribasic, Cellulose Gel, Choline Chloride, Soy Lecithin, Carrageenan, Salt (Sodium Chloride), Ascorbic Acid, Cellulose Gum, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Zinc Sulfate, Niacinamide, Manganese Sulfate, Calcium Pantothenate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Vitamin A Palmitate, Pyridoxine Hydrochloride, Riboflavin, Chromium Chloride, Folic Acid, Sodium Molybdate, Biotin, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein:

The protein source is calcium caseinate.

Calcium caseinate	100%

Fat

The fat source is a blend of two oils: high-oleic safflower and canola.

High-oleic safflower oil	70%
Canola oil	30%

The level of fat in ENSURE LIGHT meets American Heart Association (AHA) guidelines. The 3 grams of fat in ENSURE LIGHT represent 13.5% of the total calories, with 1.4% of the fat being from saturated fatty acids and 2.6% from polyunsaturated fatty acids. These values are within the AHA guidelines of $\leq$ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and $\leq$ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate

ENSURE LIGHT contains a combination of maltodextrin and sucrose. The chocolate flavor contains corn syrup as well. The mild sweetness and flavor variety (French vanilla, chocolate supreme, strawberry swirl), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Sucrose	51%
Maltodextrin	49%

Chocolate

Sucrose	47.0%
Corn Syrup	26.5%
Maltodextrin	26.5%

Vitamins and Minerals

An 8-fl-oz serving of ENSURE LIGHT provides at least 25% of the RDIs for 24 key vitamins and minerals.

Caffeine

Chocolate flavor contains 2.1 mg caffeine/8 fl oz.

E. ENSURE PLUS®

Usage: ENSURE PLUS is a high-calorie, low-residue liquid food for use when extra calories and nutrients, but a normal concentration of protein, are needed. It is designed primarily as an oral nutritional supplement to be used with or between meals or, in appropriate amounts, as a meal replacement. ENSURE PLUS is lactose- and gluten-free. Although it is primarily an oral nutritional supplement, it can be fed by tube.

Patient Conditions:

- For patients who require extra calories and nutrients, but a normal concentration of protein, in a limited volume
- For patients who need to gain or maintain healthy weight

Features

- Rich, creamy taste
- Good source of essential vitamins and minerals

Ingredients

Vanilla: ®-D Water, Corn Syrup, Maltodextrin (Corn), Corn Oil, Sodium and Calcium Caseinates, Sugar (Sucrose), Soy Protein Isolate, Magnesium Chloride, Potassium Citrate, Calcium Phosphate Tribasic, Soy Lecithin, Natural and Artificial Flavor, Sodium Citrate, Potassium Chloride, Choline Chloride, Ascorbic Acid, Carrageenan, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Chromium Chloride, Sodium Molybdate, Potassium Iodide, Sodium Selenite, Phylloquinone, Cyanocobalamin and Vitamin D_3.

Protein

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	84%

Soy protein isolate	16%

Fat

The fat source is corn oil.

Corn oil	100%

Carbohydrate

ENSURE PLUS contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla, chocolate, strawberry. coffee, buffer pecan, and eggnog), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry. lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla, strawberry, butter pecan, and coffee flavors

Corn Syrup	39%
Maltodextrin	38%
Sucrose	23%

Chocolate and eggnog flavors

Corn Syrup	36%
Maltodextrin	34%
Sucrose	30%

Vitamins and Minerals

An 8-fl-oz serving of ENSURE PLUS provides at least 15% of the RDIs for 25 key Vitamins and minerals.

Caffeine

Chocolate flavor contains 3.1 mg Caffeine/8 fl oz. Coffee flavor contains a trace amount of caffeine.

F. ENSURE PLUS® HN

Usage: ENSURE PLUS HN is a nutritionally complete high-calorie, high-nitrogen liquid food designed for people with higher calorie and protein needs or limited volume tolerance. It may be used for oral supplementation or for total nutritional support by tube. ENSURE PLUS HN is lactose- and gluten-free.

Patient Conditions:

- For patients with increased calorie and protein needs, such as following surgery or injury
- For patients with limited volume tolerance and early satiety

Features

- For supplemental or total nutrition
- For oral or tube feeding
- 1.5 CaVmL
- High nitrogen
- Calorically dense

Ingredients

Vanilla: ®-D Water, Maltodextrin (Corn), Sodium and Calcium Caseinates, Corn Oil, Sugar (Sucrose), Soy Protein Isolate, Magnesium Chloride, Potassium Citrate, Calcium Phosphate Tribasic, Soy Lecithin, Natural and Artificial Flavor, Sodium Citrate, Choline Chloride, Ascorbic Acid, Taurine, L-Carnitine, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Carrageenan, Calcium Pantothenate, Manganese Sulfate, Cupric Sulfate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Chromium Chloride, Sodium Molybdate, Potassium Iodide, Sodium Selenite, Phylloquinone, Cyanocobalamin and Vitamin D_3.

G. ENSURE® POWDER

Usage: ENSURE POWDER (reconstituted with water) is a low-residue liquid food designed primarily as an oral nutritional supplement to be used with or between meals. ENSURE POWDER is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions:

- For patients on modified diets
- For elderly patients at nutrition risk
- For patients recovering from illness/surgery
- For patients who need a low-residue diet

Features

- Convenient, easy to mix
- Low in saturated fat
- Contains 9 g of total fat and < 5 mg of cholesterol per serving
- High in vitamins and minerals
- For low-cholesterol diets
- Lactose-free, easily digested

Ingredients: ®-D Corn Syrup, Maltodextrin (Corn), Sugar (Sucrose), Corn Oil, Sodium and Calcium Caseinates, Soy Protein Isolate, Artificial Flavor, Potassium Citrate, Magnesium Chloride, Sodium Citrate, Calcium Phosphate Tribasic, Potassium Chloride, Soy Lecithin, Ascorbic Acid, Choline Chloride, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Niacinamide, Calcium Pantothenate, Manganese Sulfate, Thiamine Chloride Hydrochloride, Cupric Sulfate, Pyridoxine Hydrochloride, Riboflavin, Vitamin A Palmitate, Folic Acid, Biotin, Sodium Molybdate, Chromium Chloride, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein

The protein source is a blend of two high-biologic-value proteins: casein and soy.

Sodium and calcium caseinates	84%
Soy protein isolate	16%

Fat

The fat source is corn oil.

Corn oil	100%

Carbohydrate

ENSURE POWDER contains a combination of corn syrup, maltodextrin, and sucrose. The mild sweetness of ENSURE POWDER, plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, helps to prevent flavor fatigue and aid in patient compliance.

Vanilla

Corn Syrup	35%
Maltodextrin	35%
Sucrose	30%

H. ENSURE® PUDDING

Usage: ENSURE PUDDING is a nutrient-dense supplement providing balanced nutrition in a nonliquid form to be used with or between meals. It is appropriate for consistency-modified diets (e.g., soft, pureed, or full liquid) or for people with swallowing impairments. ENSURE PUDDING is gluten-free.

Patient Conditions:

- For patients on consistency-modified diets (e.g., soft, pureed, or full liquid)
- For patients with swallowing impairments
- **Features**
- Rich and creamy, good taste
- Good source of essential vitamins and minerals Convenient-needs no refrigeration

- Gluten-free

Nutrient Profile per 5 oz: Calories 250, Protein 10.9%, Total Fat 34.9%, Carbohydrate 54.2%

Ingredients:

Vanilla: ®-D Nonfat Milk, Water, Sugar (Sucrose), Partially Hydrogenated Soybean Oil, Modified Food Starch, Magnesium Sulfate. Sodium Stearoyl Lactylate, Sodium Phosphate Dibasic, Artificial Flavor, Ascorbic Acid, Zinc Sulfate, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Choline Chloride, Niacinamide, Manganese Sulfate, Calcium Pantothenate, FD&C Yellow #5, Potassium Citrate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, FD&C Yellow #6, Folic Acid, Biotin, Phylloquinone, Vitamin D3 and Cyanocobalamin.

Protein

The protein source is nonfat milk.

Nonfat milk	100%

Fat

The fat source is hydrogenated soybean oil.

Hydrogenated soybean oil	100%

Carbohydrate

ENSURE PUDDING contains a combination of sucrose and modified food starch. The mild sweetness and flavor variety (vanilla, chocolate, butterscotch, and tapioca) help prevent flavor fatigue. The product contains 9.2 grams of lactose per serving.

Vanilla and other nonchocolate flavors

Sucrose	56%
Lactose	27%
Modified food starch	17%

Chocolate

Sucrose	58%
Lactose	26%
Modified food starch	16%

I. ENSURE® WITH FIBER

Usage: ENSURE WITH FIBER is a fiber-containing, nutritionally complete liquid food designed for people who can benefit from increased dietary fiber and nutrients. ENSURE WITH FIBER is suitable for people who do not require a low-residue diet. It can be fed orally or by tube, and can be used as a nutritional supplement to a regular diet or, in appropriate amounts, as a meal replacement. ENSURE WITH FIBER is lactose- and gluten-free, and is suitable for use in modified diets, including low-cholesterol diets.

Patient Conditions

- For patients who can benefit from increased dietary fiber and nutrients

Features

- New advanced formula-low in saturated fat, higher in vitamins and minerals
- Contains 6 g of total fat and < 5 mg of cholesterol per serving
- Rich, creamy taste
- Good source of fiber
- Excellent source of essential vitamins and minerals
- For low-cholesterol diets
- Lactose- and gluten-free

Ingredients

Vanilla: ®-D Water, Maltodextrin (Corn), Sugar (Sucrose), Sodium and Calcium Caseinates, Oat Fiber, High-Oleic Safflower Oil, Canola Oil, Soy Protein Isolate, Corn Oil, Soy Fiber, Calcium Phosphate Tribasic, Magnesium Chloride, Potassium Citrate, Cellulose Gel, Soy Lecithin, Potassium Phosphate

Dibasic, Sodium Citrate, Natural and Artificial Flavors, Choline Chloride, Magnesium Phosphate, Ascorbic Acid, Cellulose Gum, Potassium Chloride, Carrageenan, Ferrous Sulfate, Alpha-Tocopheryl Acetate, Zinc Sulfate, Niacinamide, Manganese Sulfate, Calcium Pantothenate, Cupric Sulfate, Vitamin A Palmitate, Thiamine Chloride Hydrochloride, Pyridoxine Hydrochloride, Riboflavin, Folic Acid, Chromium Chloride, Biotin, Sodium Molybdate, Potassium Iodide, Sodium Selenate, Phylloquinone, Vitamin D_3 and Cyanocobalamin.

Protein

The protein source is a blend of two high-biologic-value proteins- casein and soy.

Sodium and calcium caseinates	80%
Soy protein isolate	20%

Fat

The fat source is a blend of three oils: high-oleic safflower, canola, and corn.

High-oleic safflower oil	40%
Canola oil	40%
Corn oil	20%

The level of fat in ENSURE WITH FIBER meets American Heart Association (AHA) guidelines. The 6 grams of fat in ENSURE WITH FIBER represent 22% of the total calories, with 2.01 % of the fat being from saturated fatty acids and 6.7% from polyunsaturated fatty acids. These values are within the AHA guidelines of $\leq$ 30% of total calories from fat, < 1 0% of the calories from saturated fatty acids, and $\leq$ 1 0% of total calories from polyunsaturated fatty acids.

Carbohydrate

ENSURE WITH FIBER contains a combination of maltodextrin and sucrose. The mild sweetness and flavor variety (vanilla, chocolate, and butter

pecan), plus VARI-FLAVORS® Flavor Pacs in pecan, cherry, strawberry, lemon, and orange, help to prevent flavor fatigue and aid in patient compliance.

Vanilla and other nonchocolate flavors

Maltodextrin	66%
Sucrose	25%
Oat Fiber	7%
Soy Fiber	2%

Chocolate

Maltodextrin	55%
Sucrose	36%
Oat Fiber	7%
Soy Fiber	2%

Fiber

The fiber blend used in ENSURE WITH FIBER consists of oat fiber and soy polysaccharide. This blend results in approximately 4 grams of total dietary fiber per 8-fl-oz can. The ratio of insoluble to soluble fiber is 95:5.

The various nutritional supplements described above and known to others of skill in the art can be substituted and/or supplemented with the PUFAs of this invention.

J. Oxepa™ Nutritional Product

Oxepa is low-carbohydrate, calorically dense enteral nutritional product designed for the dietary management of patients with or at risk for ARDS. It has a unique combination of ingredients, including a patented oil blend containing eicosapentaenoic acid (EPA from fish oil), γ-linolenic acid (GLA from borage oil), and elevated antioxidant levels.

Caloric Distribution:

- Caloric density is high at 1.5 Cal/mL (355 Cal/8 fl oz), to minimize the volume required to meet energy needs.
- The distribution of Calories in Oxepa is shown in Table 7.

Table 7. Caloric Distribution of Oxepa			
	per 8 fl oz.	per liter	% of Cal
Calories	355	1,500	---
Fat (g)	22.2	93.7	55.2
Carbohydrate (g)	25	105.5	28.1
Protein (g)	14.8	62.5	16.7
Water (g)	186	785	---

Fat:

- Oxepa contains 22.2 g of fat per 8-fl oz serving (93.7 g/L).
- The fat source is a oil blend of 31.8% canola oil, 25% medium-chain triglycerides (MCTs), 20% borage oil, 20% fish oil, and 3.2 % soy lecithin. The typical fatty acid profile of Oxepa is shown in Table 8.
- Oxepa provides a balanced amount of polyunsaturated, monounsaturated, and saturated fatty acids, as shown in Table 10.
- Medium-chain trigylcerides (MCTs) -- 25% of the fat blend -- aid gastric emptying because they are absorbed by the intestinal tract without emulsification by bile acids.

The various fatty acid components of Oxepa™ nutritional product can be substituted and/or supplemented with the PUFAs of this invention.

Table 8. Typical Fatty Acid Profile			
	% Total Fatty Acids	g/8 fl oz*	g/L*
Caproic (6:0)	0.2	0.04	0.18
Caprylic (8:0)	14.69	3.1	13.07
Capric (10:0)	11.06	2.33	9.87
Palmitic (16:0)	5.59	1.18	4.98
Palmitoleic (16:1n-7)	1.82	0.38	1.62
Stearic (18:0)	1.84	0.39	1.64

Oleic (18:1n-9)	24.44	5.16	21.75
Linoleic (18:2n-6)	16.28	3.44	14.49
α-Linolenic (18:3n-3)	3.47	0.73	3.09
γ-Linolenic (18:3n-6)	4.82	1.02	4.29
Eicosapentaenoic (20:5n-3)	5.11	1.08	4.55
n-3-Docosapentaenoic (22:5n-3)	0.55	0.12	0.49
Docosahexaenoic (22:6n-3)	2.27	0.48	2.02
Others	7.55	1.52	6.72

* Fatty acids equal approximately 95% of total fat.

Table 9. Fat Profile of Oxepa.	
% of total calories from fat	55.2
Polyunsaturated fatty acids	31.44 g/L
Monounsaturated fatty acids	25.53 g/L
Saturated fatty acids	32.38 g/L
n-6 to n-3 ratio	1.75:1
Cholesterol	9.49 mg/8 fl oz 40.1 mg/L

Carbohydrate:

- The carbohydrate content is 25.0 g per 8-fl-oz serving (105.5 g/L).
- The carbohydrate sources are 45% maltodextrin (a complex carbohydrate) and 55% sucrose (a simple sugar), both of which are readily digested and absorbed.
- The high-fat and low-carbohydrate content of Oxepa is designed to minimize carbon dioxide (CO_2) production. High CO_2 levels can complicate weaning in ventilator-dependent patients. The low level of carbohydrate also may be useful for those patients who have developed stress-induced hyperglycemia.
- Oxepa is lactose-free.

Dietary carbohydrate, the amino acids from protein, and the glycerol moiety of fats can be converted to glucose within the body. Throughout this process, the carbohydrate requirements of glucose-dependent tissues (such as the central nervous system and red blood cells) are met. However, a diet free of

carbohydrates can lead to ketosis, excessive catabolism of tissue protein, and loss of fluid and electrolytes. These effects can be prevented by daily ingestion of 50 to 100 g of digestible carbohydrate, if caloric intake is adequate. The carbohydrate level in Oxepa is also sufficient to minimize gluconeogenesis, if energy needs are being met.

Protein:

- Oxepa contains 14.8 g of protein per 8-fl-oz serving (62.5 g/L).
- The total calorie/nitrogen ratio (150:1) meets the need of stressed patients.
- Oxepa provides enough protein to promote anabolism and the maintenance of lean body mass without precipitating respiratory problems. High protein intakes are a concern in patients with respiratory insufficiency. Although protein has little effect on CO_2 production, a high protein diet will increase ventilatory drive.
- The protein sources of Oxepa are 86.8% sodium caseinate and 13.2% calcium caseinate.

All publications and patent applications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated as incorporated by reference.

The invention now being fully described, it will be apparent to one of ordinary skill in the art that many changes and modifications can be made thereto without departing from the spirit or scope of the appended claims.

(2) INFORMATION FOR SEQ ID NO:34:

(i) SEQUENCE CHARACTERISTICS:
(A) LENGTH: 757 amino acids
(B) TYPE: amino acid
(C) STRANDEDNESS: single
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: amino acid (Translation of Contig 253538a)

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:34:

What is claimed is:

1. An isolated nucleic acid comprising:

a nucleotide sequence depicted in a SEQ ID NO. 1

2. A polypeptide encoded by said nucleic acid of claim 1.

3. A purified or isolated polypeptide comprising an amino acid sequence depicted in SEQ ID NO: 2.

4. An isolated nucleic acid encoding the polypeptide of SEQ ID NO: 2.

5. An isolated nucleic acid comprising:

a nucleotide sequence which encodes a polypeptide that desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule.

6. The isoloated nucleic acid according to Claim 5, wherein said nucleotide sequence is derived from eukaryotic cell.

7. The isolated nucleic acid according to Claim 6, wherein said eukaryotic cell is a fungal cell.

8. The isolated nucleic acid according to Claim 7, wherein said fungal cell is of the genus *Mortierella.*

9. The isolated nucleic acid according to Claim 8, wherein said *Mortierella* cell is of the species *Mortierella alpina.*

10. The isolated nucleic acid according to Claim 5, wherein said nucleotide sequence anneals to a nucleotide sequence depicted in SEQ ID NO: 1.

11. The nucleic acid of claim 10, wherein said nucleotide sequence encodes an amino acid sequence depicted in SEQ ID NO: 2.

12. The nucleic acid of claim 11, wherein said amino acid sequence depicted in SEQ ID NO: 2 is selected from the group consisting of amino acid residues 30-38, 41-44, 171-175, 203-212, and 387-394.

13. An isolated or purified polypeptide which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule.

14. An isolated nucleic acid comprising:

a nucleotide sequence which is substantially identical to a sequence of at least 50 nucleotides in SEQ ID NO 1.

15. An isolated nucleic acid sequence having at least about 50% identity to SEQ ID NO 1.

16. A nucleic acid construct comprising:

a nucleotide sequence depicted in a SEQ ID NO: 1 linked to a heterologous nucleic acid.

17. A nucleic acid construct comprising:

a nucleotide sequence depicted in a SEQ ID NO: 1 operably linked to a promoter.

18. The nucleic acid construct of claim 17, wherein said promoter is functional in a microbial cell.

19. The nucleic acid construct of claim 18, wherein said microbial cell is a yeast cell.

20. The nucleic acid construct of claim 17, wherein said nucleotide sequence is derived from a fungus.

21. The nucleic acid according to Claim 19, wherein said fungus is of the genus *Mortierella*.

22. The nucleic acid according to Claim 20, wherein said fungus is of the species *Mortierella alpina*.

23. A nucleic acid construct comprising:

a nucleotide sequence which encodes a polypeptide comprising an amino acid sequence which corresponds to or is complementary to an amino acid sequence depicted in SEQ ID NO: 2, wherein said nucleotide sequence is operably linked to a promoter which is functional in a host cell, wherein said nucleotide

sequence encodes a polypeptide which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of a fatty acid molecule.

24. A nucleic acid construct comprising:

a nucleotide sequence which encodes a functionally active Δ5-desaturase, said desaturase having an amino acid sequence which corresponds to or is complementary to all of or a portion of an amino acid sequence depicted in a SEQ ID NO: 2, wherein said nucleotide sequence is operably linked to a promoter functional in a host cell.

25. A recombinant yeast cell comprising:

a nucleic construct according to Claim 23 or Claim 24.

26. The recombinant yeast cell according to Claim 25, wherein said yeast cell is a *Saccharomyces* cell.

27. A host cell comprising:

at least one copy of a nucleotide sequence which encodes a polypeptide which converts dihomo-γ-linolenic acid to arachidonic acid, wherein said microbial cell or an ancestor of said microbial cell was transformed with a vector comprising said nucleotide sequence, and wherein said nucleotide sequence is operably linked to a promoter functional in said host cell.

28. The microbial cell according to Claim 27, wherein said cell is a host cell selected from the group consisting of a fungal cell and an algal cell.

29. The microbial cell according to Claim 28, wherein said fungal cell is a yeast cell and said algae cell is marine algal cell.

30. The microbial cell according to Claim 27, wherein said cell is enriched for 20:3 fatty acids as compared to a host cell which is devoid of said nucleotide sequence.

31. The microbial cell according to Claim 27, wherein said cell is enriched for 20:4 or ω-3 20:4 fatty acids as compared to a host cell which is devoid of said DNA sequence.

32. The microbial cell according to Claim 27, wherein said cell is enriched for 20:5 fatty acids as compared to a host cell which is devoid of said DNA sequence.

33. The microbial cell according to Claim 27, wherein said cell has an altered amount of 20:3 (8, 11, 14) fatty acid as compared to an untransformed microbial cell.

34. A method for production of arachidonic acid in a microbial cell culture, said method comprising:

growing a microbial cell culture having a plurality of microbial cells, wherein said microbial cells or ancestors of said microbial cells were transformed with a vector comprising one or more nucleic acids having a nucleotide sequence which encodes a polypeptide which converts dihomo-γ-linolenic acid to arachidonic acid, wherein said one or more nucleic acids are operably linked to a promoter, under conditions wherein said one or more nucleic acids are expressed and arachidonic acid is produced in said microbial cell culture.

35. The method of Claim 34, wherein said polypeptide is an enzyme which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule.

36. The method of Claim 34, wherein said nucleotide sequence is derived from a *Mortierella species.*

37. The method according to Claim 34, wherein said dihomo-γ-linolenic acid is exogenously supplied.

38. The method according to Claim 34, wherein said microbial cells are yeast cells.

39. The method according to Claim 38, wherein said yeast cells are *Saccharomyces species* cells.

40. The method according to Claim 34, wherein said conditions are inducible.

41. A recombinant yeast cell which converts greater than about 5% of a 20:3 fatty acid to a 20:4 fatty acid.

42. A nucleic acid probe comprising:

a nucleotide sequence as represented by SEQ ID NO:1.

43. A host cell comprising:

a nucleic acid construct according to Claim 23 or Claim 24.

44. A host cell comprising:

a vector which includes a nucleic acid which encodes a fatty acid desaturase derived from *Mortierella alpina*, wherein said fatty acid desaturase comprises an amino acid sequence represented by SEQ ID NO:2, wherein said nucleic acid is operably linked to a promoter.

45. The host cell according to Claim 44, wherein said host cell is a eukaryotic cell.

46. The host cell according to Claim 45, wherein said eukaryotic cell is selected from the group consisting of a mammalian cell, a plant cell, a fungal cell, an avian cell and an algal cell.

47. The host cell according to Claim 45, wherein said host cell contains dihomo-gamma-linolenic acid.

48. The host cell according to Claim 45, wherein said host cell contains EPA.

49. The host cell according to Claim 44, wherein said promoter is exogenously supplied.

50. A method for desaturating a dihomo-γ-linolenic acid, said method comprising:

culturing a recombinant microbial cell according to Claim 37, under conditions suitable for expression of polypeptide encoded by said nucleic acid, wherein said host cell further comprises a fatty acid substrate of said polypeptide.

51. A fatty acid desaturated by the method according to Claim 50.

52. An oil comprising a fatty acid according to Claim 51.

53. A method for obtaining altered long chain polyunsaturated fatty acid biosynthesis comprising the steps of:

growing a microbe having cells which contain a transgene which encodes a transgene expression product which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule, wherein said trangene is operably associated with an expression control sequence, under conditions whereby said transgene is expressed, whereby long chain polyunsaturated fatty acid biosynthesis in said cells is altered.

54. A method for obtaining altered long chain polyunsaturated fatty acid biosynthesis comprising the steps of:

growing a microbe having cells which contain a transgene, derived from a fungus or algae, which encodes a transgene expression product which desaturates a fatty acid molecule at carbon 5 from the carboxyl end of said fatty acid molecule, wherein said trangene is operably associated with an expression control sequence, under conditions whereby said one or more transgenes is expressed, whereby long chain polyunsaturated fatty acid biosynthesis in said cells is altered.

55. The method according to claims 53 or 54, wherein said long chain polyunsaturated fatty acid is selected from the group consisting of ARA, DGLA and EPA.

56. A microbal oil or fraction thereof produced according to the method of claims 53 or 54.

57. A method of treating or preventing malnutrition comprising administering said microbal oil of claim 56 to a patient in need of said treatment or prevention in an amount sufficient to effect said treatment or prevention.

58. A pharmaceutical composition comprising said microbal oil or fraction of claim 56 and a pharmaceutically acceptable carrier.

59. The pharmaceutical composition of claim 58, wherein said pharmaceutical composition is in the form of a solid or a liquid.

60. The pharmaceutical composition of claim 59, wherein said pharmaceutical composition is in a capsule or tablet form.

61. The pharmaceutical composition of claim 58 further comprising at least one nutrient selected from the group consisting of a vitamin, a mineral, a carbohydrate, a sugar, an amino acid, a free fatty acid, a phospholipid, an antioxidant, and a phenolic compound.

62. A nutritional formula comprising said microbal oil or fraction thereof of claim 56.

63. The nutritional formula of claim 62, wherein said nutritional formula is selected from the group consisting of an infant formula, a dietary supplement, and a dietary substitute.

64. The nutritional formula of claim 63, wherein said infant formula, dietary supplement or dietary supplement is in the form of a liquid or a solid.

65. An infant formula comprising said microbal oil or fraction thereof of claim 56.

66. The infant formula of claim 65 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

67. The infant formula of claim 66 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

68. A dietary supplement comprising said microbal oil or fraction thereof of claim 56.

69. The dietary supplement of claim 68 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

70. The dietary supplement of claim 69 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

71. The dietary supplement of claim 68 or claim 70, wherein said dietary supplement is administered to a human or an animal.

72. A dietary substitute comprising said microbal oil or fraction thereof of claim 56.

73. The dietary substitute of claim 72 further comprising at least one macronutrient selected from the group consisting of coconut oil, soy oil, canola oil, mono- and diglycerides, glucose, edible lactose, electrodialysed whey, electrodialysed skim milk, milk whey, soy protein, and other protein hydrolysates.

74. The dietary substitute of claim 73 further comprising at least one vitamin selected from the group consisting of Vitamins A, C, D, E, and B complex; and at least one mineral selected from the group consisting of calcium, magnesium, zinc, manganese, sodium, potassium, phosphorus, copper, chloride, iodine, selenium, and iron.

75. The dietary substitute of claim 72 or claim 74, wherein said dietary substitute is administered to a human or animal.

76. A method of treating a patient having a condition caused by insuffient intake or production of polyunsaturated fatty acids comprising administering to said patient said dietary substitute of claim 72 or said dietary supplement of claim 68 in an amount sufficient to effect said treatment.

77. The method of claim 72, wherein said dietary substitute or said dietary supplement is administered enterally or parenterally.

78. A cosmetic comprising said microbal oil or fraction thereof of claim 56.

79. The cosmetic of claim 78, wherein said cosmetic is applied topically.

80. The pharmaceutical composition of claim 58, wherein said pharmaceutical composition is administered to a human or an animal.

81. An animal feed comprising said microbal oil or fraction thereof of claim 56.

82. The method of claim 54 wherein said fungus is *Mortierella species*.

83. The method of claim 82 wherein said fungus is *Mortierella alpina*.

84. An isolated nucleotide sequence selected from the group consisting of SEQ ID NO:13 and SEQ ID NO:15.

85. An isolated nucleotide sequence from the group consisting of SEQ ID NO:7 and SEQ ID NO:19.

86. An isolated nucleotide sequence comprising a nucleotide sequence selected from the group consisting of: SEQ ID NO:13; SEQ ID NO: 15; SEQ ID NO:17; SEQ ID NO:19; SEQ ID NO:21; SEQ ID NO:22; SEQ ID NO:23; SEQ ID NO:24; SEQ ID NO:25; SEQ ID NO:26 and SEQ ID NO:27.

87. An isolated peptide sequence comprising a peptide sequence selected from the group consisting of: SEQ ID NO:14; SEQ ID NO:16; SEQID NO:18; SEQ ID NO:20; SEQ ID NO:28; SEQ ID NO:29; SEQ ID NO:30; SEQ ID NO:31; SEQ ID NO:32; SEQ ID NO:33 and SEQ ID NO:34.

88. Purified polypeptides produced from the nucleotide sequences of claims 84-86.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US 98/07422

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [X] Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 57, 76, 77 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. [ ] Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. [ ] Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. [ ] As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. [X] As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. [ ] As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. [ ] No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

[ ] The additional search fees were accompanied by the applicant's protest.

[ ] No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-83

   Nucleic acids, polypeptides, constructs comprising delta-5 desaturase according to SEQ ID NO: 1,2 derived from the fungus Mortierella alpina. Recombinant host cells comprising said nucleic acids or constructs.
   Methods for the production of arachidonic acid in a microbial cell comprising a cell containing a vector encoding an enzyme activity which converts dihomo-y-linolenic acid to arachidonic acid, preferentially a delta-5 desaturase, more preferentially from Mortierella.
   A recombinant yeast cell converting more than 5% of a 20:3 fatty acid to a 20:4 fatty acid.
   Methods for desaturating dihomo-y-linolenic acid using said microbial cells, fatty acids and oils obtained thereby.
   Methods for obtaining altered long chain polyunsaturated fatty acid biosynthesis using microbes comprising delta-5 desaturase derived from fungi or algae.
   Microbial oils derived from thereof and their use for therapeutical, nutritional, and cosmetical purposes, as well as products derived therefrom.

2. Claims: 84,86-88 partially

   An isolated sequence comprising the sequence of SEQ ID NO: 13, purified polypeptides produced thereof, esp. comprising SEQ ID NO: 14.

3. Claims: 84, 86-88 partially

   An isolated nucleotide comprising the sequence of SEQ ID NO: 15, purified polypeptides produced thereof, esp. comprising SEQ ID NO: 16.

4. Claims: 85 completely, 86-88 partially

   An isolated nucleotide sequence consisting of SEQ ID NO: 17 and SEQ ID NO: 19, purified polypeptides produced therefrom, esp. comprising SEQ ID NO: 18 and SEQ ID NO: 20.

TITLE MODIFIED
see front page

0249676

<u>A method for the expression of genes in plants, parts of plants, and plant cell cultures, and DNA fragments, plasmids, and transformed microorganisms to be used when carrying out the method, as well as the use thereof for the expression of genes in plants, parts of plants, and plant cell cultures.</u>

The invention relates to a novel method for the expression of genes in plants, parts of plants, and plant cell cultures, as well as DNA fragments and plasmids comprising said DNA fragments to be used when carrying out the method. The invention furthermore relates to transformed plants, parts of plants and plant cells.

The invention relates to this method for the expression of genes of any origin under control of an inducible, root nodule specific promoter.

The invention relates especially to this method for the expression of root nodule-specific genes in transformed plants including both leguminous plants and other plants.

The invention relates furthermore to DNA fragments comprising an inducible plant promoter to be used when carrying out the method, as well as plasmids comprising said DNA fragments.

In the specification i.a. the following terms are used:

Root nodule-specific genes: Plant genes active only in the root nodules of leguminous plants, or

genes with an increased expression in root nodules. Root nodule-specific plant genes are expressed at predetermined stages of development and are activated in a coordinated manner during the symbiosis whereby a nitrogen fixation takes place and the fixed nitrogen is utilized in the metabolism of the plant.

Inducible plant promoter: Generally is meant a promoter-active 5' flanking region from plant genes inducible from a low activity to a high activity. In relation to the present invention "inducible plant promoter" means a promoter derived from, contained in or being identical with a 5' flanking region including a leader sequence of root nodule-specific genes and being capable of promoting and regulating the expression of a gene as characterised in relation to the present invention.

Leader sequence: Generally is meant a DNA sequence being transcribed into a mRNA, but not further translated into protein. The leader sequence comprises thus the DNA fragment from the start of the transcription to the ATG codon constituting the start of the translation. In relation to the present invention "leader sequence" means a short DNA fragment contained in the above inducible plant promoter and typically comprising 40-70 bp and which may comprise sequences being targets for a posttranscriptional regulation.

Promoter region: A DNA fragment containing a promoter which comprises target sequences for RNA polymerase as well as possible activation regions

comprising target sequences for transcriptional effector substances. In the present invention, target sequences for transcriptional effectors may also be situated 3′ to the promoter, i.e. in the coding sequences, the intervening sequences or on the 3′ flanking region of a root nodule-specific gene.

Furthermore a number of molecular-biological terms generally known to persons skilled in the art are used, including the terms stated below:

CAP (addition) site: The nucleotide of the 5′ end of the transcript where 7-methylGTP is added; In the Figures often given also as an asterisk *-marked nucleotide on a given nucleotide sequence.

DNA sequence or DNA segment: A linear array of nucleotides interconnected through phosphodiester bonds between the 3′ and 5′ carbon atoms of adjacent pentoses.

Expression: The process undergone by a structural gene to produce a polypeptide. It is a combination of transcription and translation as well as possible posttranslational modifications.

Flanking regions: DNA sequences surrounding coding regions. 5′ flanking regions contain a promoter. 3′ flanking regions may contain a transcriptional terminator etc.

Gene: A DNA sequence composed of three or four parts, viz. (1) the coding sequence for the gene

product, (2) the sequences in the promoter region which control whether or not the gene will be expressed, (3) those sequences in the 3' end conditioning the transcriptional termination and optionally polyadenylation, as well as (4) intervening sequences, if any.

Intervening sequences: DNA sequences within a gene which are not coding for any peptide fragment. The intervening sequences are transcribed into pre-mRNA and are eliminated by modification of pre-mRNA into mRNA. They are also called introns.

Chimeric gene: A gene composed of parts from various genes. E.g. the chimeric Lbc_3-5'-3'-CAT is composed of a chloroamphenicolacetyltransferase-coding sequence deriving from E. coli and 5' and 3' flanking regulatory regions of the Lbc_3 gene of soybean.

Cloning: The process of obtaining a population of organisms or DNA sequences deriving from one such organism or sequence by asexual reproduction, or more particular a process of isolating a particular organism or part thereof, and the propagation of this subfraction as a homogeneous population.

Coding sequences: DNA sequences determining the amino acid sequence of a polypeptide.

Cross-inoculation group: A group of leguminous plant species capable of producing functionally active root nodules with Rhizobium bacteria isolated from root nodules of other species of the group.

Leghemoglobin (Lb): An oxygen-binding protein exclusively synthesized in root nodules. The Lb proteins regulate the oxygen partial pressure in the root nodule tissue and transport oxygen to the bacteroides. In this manner the oxygen-sensitive nitrogenase enzyme is protected. The Lb genes are root nodule-specific genes.

Messenger-RNA (mRNA): RNA molecule produced by transcription of a gene and possibly modification of mRNA. The mRNA molecule mediates the genetic message determining the amino acid sequence of a polypeptide by part of the mRNA molecule being translated into said peptide.

Downstream: A position in a DNA sequence. It is defined relative to the transcriptional direction 5'- 3' of the gene relative to which the position is stated. The 3' flanking region is thus positioned downstream of the gene.

Nucleotide: A monomeric unit of DNA or RNA consisting of a sugar moiety (pentose), a phosphate, and a nitrogeneous heterocyclic base. The base is linked to the sugar moiety via a glycosidic bond (1' carbon of the pentose), and this combination of base and sugar is a nucleoside. The base characterises the nucleotide. The four DNA bases are adenine (A), guanine (G), cytosine (C), and thymine (T). The four RNA bases are A, G, C, and uracil (U).

Upstream: A position in a DNA sequence. It is defined relative to the transcriptional direction 5'- 3' f the gene relative to which the position

is stated. The 5' flanking region is thus positioned upstream of this gene.

Plant transformation: Processes leading to incorporation of genes in the genome of plant cells in such a manner that these genes are reliably inherited through mitosis and meiosis or in such a manner that these genes are only maintained for short periods.

Plasmid: An extra-chromosomal double-stranded DNA sequence comprising an intact replicon such that the plasmid is replicated in a host cell. When the plasmid is placed within a unicellular organism, the characteristics of that organism are changed or transformed as a result of the DNA of the plasmid. For instance a plasmid carrying the gene for tetracycline resistance (Tc^R) transforms a cell previously sensitive to tetracycline into one which is resistant to it. A cell transformed by a plasmid is called a transformant.

Polypeptide: A linear array of amino acids interconnected by means of peptide bonds between the α-amino and carboxy groups of adjacent amino acids.

Recombination: The creation of a new DNA molecule by combining DNA fragments of different origin.

Homologous recombination: A recombination between sequences showing a high degree of homology.

Replication: A process reproducing DNA molecules.

Replicon: A self-replicating genetic element possessing an origin for the initiation of DNA replication and genes specifying the functions necessary for a control and a replication thereof.

Restriction fragment: A DNA fragment resulting from double-stranded cleavage by an enzyme recognizing a specific target DNA sequence.

RNA polymerase: Enzyme effecting the transcription of DNA into RNA.

Root nodule: Specialized tissue resulting from infection of mainly roots of leguminous plants with Rhizobium bacteria. The tissue is produced by the host plant and comprises therefore plant cells whereas the Rhizobium bacteria upon infection are surrounded by a plant cell membrane and differentiate into bacteroides. Root nodules are produced on other species of plants upon infection of nitrogen-fixing bacteria not belonging to the Rhizobium genus. Root nodule-specific plant genes are also expressed in these nodules.

Southern-hybridization: Denatured DNA is transferred upon size separation in agarose gel to a nitrocellulose membrane. Transferred DNA is analysed for a predetermined DNA sequence or a predetermined gene by hybridization. This process allows a binding of single-stranded, radioactively marked DNA sequences (probes) to complementary single-stranded DNA sequences bound on the membrane. The position of DNA fragments on the membrane binding the probe can subsequently be detected n an X-ray film.

Symbiotic nitrogen fixation: The relationship whereby bacteroides of root nodules convert the nitrogen (dinitrogen) of the air into ammonium utilized by the plant while the plant provides the bacteroides with carbon compounds as a carbon source.

Symbiont: One part of a symbiotic relationship, and especially *Rhizobium* is called the microsymbiont.

Transformation: The process whereby a cell is incorporating a DNA molecule.

Translation: The process of producing a polypeptide from mRNA or:
the process whereby the genetic information present in a mRNA molecule directs the order of specific amino acids during the synthesis of a polypeptide.

Transcription: The method of synthesizing a complementary RNA sequence from a DNA sequence.

Vector: A plasmid, phage DNA or other DNA sequences capable of replication in a host cell and having one or a small number of endonuclease recognition sites at which such DNA sequences may be cleaved in a determinable manner without loss of an essential biological function.

Traditional plant breeding is based on repeated crossbreeding of plant lines individually carrying desired qualities. The identification of progeny lines carrying all the desired qualities is a particularly time-consuming process as the biochemical

and genetic basis of the qualities is usually unknown. New lines are therefore chosen according to their phenotype, usually after a screening of many lines in field experiments.

Through the ages a direct connection has existed between the state of nutrition, i.e. the health, of the population and the agricultural possibility of ensuring a sufficient supply of assimilable nitrogen in order to obtain satisfactory yields. Already in the seventeenth century it was discovered that plants of the family leguminosae including beyond peas also beans, lupins, soybean, bird's-foot trefoil, vetches, alfalfa, sainfoin, and trefoil had an ability of improving crops grown on the habitat of these plants. Today it is known that the latter is due to the fact that the members of the plants of the family leguminosae are able to produce nitrogen reserves themselves. On the roots they carry bacteria with which they live in symbiosis.

An infection of the roots of these leguminous plants with <u>Rhizobium</u> bacteria causes a formation of root nodules able to convert atmospheric nitrogen into bound nitrogen, which is a process called nitrogen fixation.

Atmospheric nitrogen is thereby converted into forms which can be utilized by the host plant as well as by the plants later on growing on the same habitat.

In the nineteenth century the above possibility was utilized f r the supply of nitrogen in order to achieve a novel increase of the crop yield.

The later further increases in the yield have, however, especially been obtained by means of natural fertilizers and nitrogen-containing synthetic fertilizers. The resulting pollution of the environment makes it desirable to provide alternative possibilities of ensuring the supply of nitrogen necessary for the best possible yields obtainable.

It would thus be valuable to make an improvement possible of the existing nitrogen fixation systems in leguminous plants as well as to allow an incorporation of nitrogen fixation systems in other plants.

The recombinant DNA technique and the plant transformation systems developed render it now possible to provide plants with new qualities in a well-controlled manner. These characteristics can derive from not only the same plant species, but also from all other prokaryotic or eukaryotic organisms. The DNA techniques allow further a quick and specific identification of progeny lines carrying the desired qualities. In this manner a specific plant line can be provided with one or more desired qualities in a quick and well-defined manner.

Correspondingly, plant cells can be provided with well defined qualities and subsequently be maintained as plant cell lines by means of known tissue culture methods. Such plant cells can be utilized for the production of chemical and biological products of particular interest such as dyes, flavours, aroma components, plant hormones, pharmaceutical

products, primary and secondary metabolites as well as polypeptides (enzymes).

A range of factors and functions necessary for biological production of a predetermined gene product are known. Both the initiation and regulation of transcription as well as the initiation and regulation of posttransscriptional processes can be characterised.

At the gene level it is known that these functions are mainly carried out by 5' flanking regions. A wide range of 5' flanking regions from prokaryotic and eukaryotic genes has been sequenced, and in view inter alia thereof a comprehensive knowledge has been provided of the regulation of gene expression and of the sub-regions and sequences being of importance for the regulation of expression of the gene. Great differences exist in the regulatory mechanism of prokaryotic and eukaryotic organisms, but many common features apply to the two groups.

The regulation of the expression of gene may take place on the transscriptional level and is then preferably exerted by regulating the initiation frequency of transscription. The latter is well-known and described inter alia by Benjamin Lewin, Gene Expression, John Wiley & Sons, vol. I, 1974, vol. II, Second Edition 1980, vol. III, 1977. As an alternative the regulation may be exerted at the posttransscriptional level, e.g. by the regulation of the frequency of the translation initiation, at the rate of the translation, and of the termination of the translation.

The present invention is based on the surprising finding that 5' flanking regions of root nodule-specific genes, exemplified by the 5' flanking region of the soybean leghemoglobin Lbc_3 gene, can be used for inducible expression of a foreign gene in an alien leguminous plant. The induction and regulation of the promoter is preferably carried out in the form of a regulation and induction at the transscriptional level and differs thereby from the inducability stated in Patent Application No. 86114704.9, the latter inducability preferably being carried out at the translation level.

The transscription of both the Lbc_3 gene of the soybean and of a chimeric Lbc_3 gene transferred to bird's-foot trefoil starts at a low level immediately upon the appearance of the root nodules on the plant roots. Subsequently, a high increase of the transscription takes place immediately before the root nodules turn red. The transcription of a range of other root nodule-specific genes is initiated exactly at this time. The simultaneous induction of the transscription of the Lb genes and other root nodule-specific genes means that a common DNA sequence(s) must be present for the various genes controlling this pattern of expression. Thus the leghemoglobin-c_3 gene is a representative of one class of genes and the promoter and the leader sequence, target areas for activation as well as the control elements of the organ specificity of the Lbc_3 gene are representatives of the control elements of a complete gene class.

The promoter of the 5' flanking regions of the Lb genes functions in soybeans and is responsible for the transcription of the Lb genes in root nodules. It is furthermore known, that the efficiency of both the transcription initiation and the subsequent translation initation on the leader sequence of the Lb genes is high as the Lb proteins constitute approximately 20% of the total protein content in root nodules.

The sequence of 5' flanking regions of the four soybean leghemoglobin genes Lba, Lbc_1, Lbc_2, and Lbc_3 appears from the enclosed sequence scheme, scheme 1, wherein the sequences are stated in such a manner that the homology between the four 5' flanking regions appears clearly.

In the sequence scheme "-" indicates that no base is present in the position in question. The names of the genes and the base position counted upstream from the ATG start codon are indicated to the right of the sequence scheme. Furthermore the important sequences have been underlined.

As it appears from the sequence scheme a distinct degree of homology exists between the four 5' flanking regions, and in the position 23-24 bp upstream from the CAP addition site they all contain a TATATAAA sequence corresponding to the "TATA" box which in eukaryotic cells usually are located a corresponding number of bp upstream from the CAP addition site. Furthermore a CCAAG sequence is present 64-72 bp upstream from the CAP addition site, said sequence corresponding to the "CCAAT"

box usually located 70-90 bp upstream from the CAP addition site. From the CAP addition site to the translation start codon, ATG, leader sequences of 52-59 bp are present and show a distinct degree of homology of approx. 75-80%.

In accordance with the present invention it has furthermore been proved, exemplified by the Lbc_3 gene, that the 5' flanking regions of the soybean leghemoglobin genes are functionally active in other plant species. The latter has been proved by fusioning the E. coli chloroamphenicol acetyl transferase (CAT) gene with the 5' and 3' flanking regions of the soybean Lbc_3 gene in such a manner that the expression of the CAT gene is controlled by the Lb promoter. This fusion fragment was cloned into the integration vectors pAR1 and pAR22, whereby the plasmids pAR29 and pAR30 were produced. Through homologous recombination the latter plasmids were integrated into the Agrobacterium rhizogenes T DNA region. The transformation of Lotus corniculatus (bird's-foot trefoil) plants, i.e. transfer of the T DNA region, was obtained by wound infection on the hypokotyl. Roots developed from the transformed plant cells were cultivated in vitro and freed from A. rhizogenes bacteria by means of antibiotics. Completely regenerated plants were produced by these root cultures in a conventional manner through somatic embryogenesis or organogenesis.

Regenerated plants were subsequently inoculated with Rhizobium loti bacteria and root nodules for analysis were harvested. Transcription and translation of the chimeric Lbc_3 CAT gene could subse-

quently be detected in root nodules on transformed plants as the activity of the produced chloroamphenicol acetyl transferase enzyme.

The conclusion can subsequently be made that the promoter-containing 5' flanking regions of root nodule-specific genes exemplified by the soybean Lbc_3 promoter are functionally active in foreign plants. The latter is a surprising observation as root nodules are only developed as a consequence of a very specific interaction between the leguminous plant and its corresponding <u>Rhizobium</u> microsymbiont.

Soybeans produce nodules only upon infection by the species <u>Rhizobium japonicum</u> and <u>Lotus corniculatus</u> only upon infection by the species <u>Rhizobium loti</u>. Soybean and <u>Lotus corniculatus</u> belong therefore to two different cross-inoculation groups, each group producing root nodules by means of two different <u>Rhizobium</u> species. The expression of a chimeric soybean gene in <u>Lotus corniculatus</u> proves therefore an unexpected universal regulatory system applying to the expression of root nodule-specific genes. The regulatory DNA sequences involved can be placed on the 5' and 3' flanking regions of the genes, here exemplified by the 2.0 Kb 5' and 0.9 Kb 3' flanking regions of the Lbc_3 gene. This surprising observation allows the use of root nodule-specific promoters and regulatory sequences in any other plant species and any other plant cell line.

In other experiments the 5' flanking region of the nodule-specific N23 gene was fused to the CAT gene

and the Lbc_3 3' flanking region in such a manner that the expression of the CAT gene is controlled by the N23 promoter. This fusion fragment was cloned into the integration vector pAR22 producing the plasmid N23-CAT which was subsequently recombined into A.rhizogenes and transferred to Lotus corniculatus and Trifolium repens (white clover) by the previously described method. The root nodule-specific expression of the transferred N23-CAT gene obtained in L. corniculatus infected with Rhizobium loti and in T.repens infected with Rhizobium trifolii further demonstrated that expression of root nodule-specific genes is independent of the plant species and Rhizobium species. A universal regulatory system therefore regulates the expression of root nodule-specific genes in the different symbiotic systems formed between legumes and the Rhizobium species of the various cross-inoculation groups.

It is known from European Patent Application EP 122,791.A1 that plant genes from one species, by Agrobacterium mediated transformation, can be transferred into a different plant species. It is also known from EP 122,791.A1 that a transferred gene encoding the seed storage protein "Phaseolin" can be expressed into tobacco and alfalfa. From the literature it is also known that this expression is seed specific (Sengupta-Gopalan et al. 1985, Proc. Natl. Acad. Sci. 82, 33203324).

The present invention therefore relates to a novel method for the expression of transferred genes in a root nodule-specific manner, using DNA regulatory

sequences from the 5' promoter region, the coding region, or the 3' flanking region of root nodule-specific genes, here exemplified by the leghemoglobin Lbc_3 gene and the N23 gene. This method is distinct from both the method of Agrobacterium mediated transformation and expression of the seed storage protein phaseolin gene characterised in EP 122,791.A1. Expression of the transferred phaseolin gene in EP 122,791.A1 only demonstrates that the phaseolin gene family with its particular regulatory requirements can be expressed in tobacco and alfalfa. It does not demonstrate nor predict that any other genes with their particular regulatory requirements can be expressed in any other plants or plant tissue.

An object of the present invention is to provide a possibility of expressing desired genes in plants, parts of plants, and plant cell cultures.

A further object of the invention is to render it possible to express genes of any origin by the control of an inducible root nodule-specific promoter.

A particular object of the invention is to provide a possibility of expressing desired genes in leguminous plants.

A still further particular object of the invention is to provide a possibility of expressing root nodule-specific genes in non-leguminous plants.

Further objects of the invention are to improve the

existing nitrogen-fixing systems in leguminous plants as well as to incorporate nitrogen-fixing systems in other plants.

A further object of the invention is to provide a possibility of in certain cases allowing the use of specific sequences of the 3' flanking region, of the coding sequence, and of intervening sequences to influence the regulation of the root nodule-specific promoter.

Furthermore it is an object of the invention to provide plasmids comprising the above mentioned inducible plant promoter.

Further objects of the invention appear immediately from the following description.

The method according to the invention for the expression of genes in plants, parts of plants, and plant cell cultures is carried out by introducing into a cell thereof a recombinant DNA segment containing both the gene to be expressed and a 5' flanking region comprising a promoter sequence, and optionally a 3' flanking region, and culturing of the transformed cells in a growth medium, said method being characterised by using as the recombinant DNA segment a DNA fragment comprising an inducible plant promoter (as defined) from root nodule-specific genes. If desired the transformed cells are regenerated to plants.

The method according to the invention allows in a well defined manner an expression f foreign genes

in plants, parts of plants, and plant cell cultures, in this connection especially genes providing the plants with desired properties such as for instance a resistance to plant diseases and increased content of valuable polypeptides.

A further use is the preparation of valuable products such as for instance dyes, flavourings, plant hormones, pharmaceutical products, primary and secondary metabolites, and polypeptides by means of the method according to the invention in plant cell cultures and plants.

By using the method according to the invention for the expression of root nodule-specific genes it is possible to express root nodule-specific genes necessary for the formation of an active nitrogen-fixing system both in leguminous plants and other plants. The correct developmental control, cf. Example 8, allows the establishment of a symbiotic nitrogen-fixing system in non-leguminous plants. In this manner it is surprisingly possible to improve the existing nitrogen-fixing systems in leguminous plants as well as to incorporate nitrogen-fixing systems in other plants.

The use of the method according to the invention for the expression of foreign genes in root nodules renders it possible to provide leguminous plants with improved properties such as resistance to herbicides and resistance to diseases and pest.

According to a particular embodiment of the method according to the invention a DNA fragm nt is used

which comprises an inducible plant promoter and which is identical with, derived from, or comprises 5′ flanking regions of leghemoglobins genes. In this manner the expression of any gene is obtained.

Examples of such DNA fragments are DNA fragments of the four 5′ flanking regions of the soybean leghemoglobin genes, viz.

```

This sequence is positioned on the 0.9 Kb 3′ flanking region used according to the invention. A particular embodiment of the invention is therefore

the use of sequences of this region exerting or mediating the regulation characterised by the invention of root nodule-specific promoter regions.

In a preferred embodiment of the method according to the invention a region is used of the coding sequence or intervening sequence of root nodule-specific genes, in particular sequences of the coding sequence or the intervening sequence capable of influencing the regulation of a promotor of the root nodule-specific genes or capable of influencing the yield of the desired gene product in another manner.

Examples of such coding sequences and intervening sequences are the four leghemoglobin genes of soybean, viz.

Lba with the sequence:

```
                                                                      120
                                                                      VAL
                                                                  ATG/GTT

The amino acid sequence of the Lbc_3 protein is indicated above the coding sequence.

The present invention furthermore deals with a novel DNA fragment comprising an inducible plant promoter to be used when carrying out the method according to the invention, said DNA fragment being characterised by being identical with, derived from or comprising a 5' flanking region of root nodule-specific genes. Examples of such DNA fragments are DNA fragments being identical with, derived from or comprising a 5' flanking region of plant leghemoglobin genes. Preferred examples are according to the invention DNA fragments being identical with, derived from or comprising a 5' flanking region of the four soybean leghemoglobin genes, viz.:

ATTAATG
```

The invention relates furthermore to any plasmid to be used when carrying out the method according to the invention and characterised by comprising a DNA fragment containing an inducible plant promoter as herein defined. Particular examples of suitable plasmids according to the invention are pAR11, pAR29, pAR30, and N23-CAT, cf. Examples 3, 4, and 11. These plasmids allow recombination into the A. rhizogenes T DNA region.

The invention relates furthermore to any Agrobacterium strain to be used in connection with the invention and characterised by comprising a DNA fragment comprising an inducible plant promoter of root nodule-specific genes built into the T DNA region and therefore capable of transforming the inducible promoter into plants. Particular examples of bacterium strains according to the invention are the A. rhizogenes strains AR1127 carrying pAR29, AR1134 carrying pAR30, AR1000 carrying pAR11, and AR204-N23-CAT carrying N23-CAT.

It is obvious that the patent protection of the present invention is not limited by the embodiments stated above.

Thus the invention employs not exclusively 5' flanking regions of soybean leghemoglobin genes. It is well-known that the leghemoglobin genes of all leguminous plants have the same function, cf. Appleby (1974) in The Biology of Nitrogen Fixation, Quispel. A. Ed. North-Holland Publishing Company, Amsterdam, Oxford, pages 499-554, and concerning the kidney bean PvLb1 gene it has furthermore been

proved that a high degree of homogoly exists with the sequences of the soybean Lbc_3 gene. It is also known that the expression of other root nodule-specific genes is regulated in a similar manner like the leghemoglobin genes. The invention includes thus the use of 5' flanking regions of leghemoglobin genes or other root nodule-specific genes of all plants in case the use of such DNA fragments makes the expression of a desired gene product the subject matter of the regulation characterised by the present invention.

The present invention allows also the use of such fragments of any origin which under natural conditions exert or mediate the regulation characterised by the present invention. The latter applies especially to such fragments which can be isolated from DNA fragments from gene libraries or genomes through hybridization with labelled sequences of 5' flanking regions of soybean leghemoglobin genes.

It is well-known that it is possible to alter nucleotide sequences of non-important sub-regions of 5' flanking regions without causing an alteration of the promoter activity and the regulation. It is also well-known that an alteration of sequences of important subregions of 5' flanking regions renders it possible to alter the binding affinities between nucleotide sequences and the factors or effector substances necessary or responsible for the transcription initation and the translation initiation and consequently to improve the promoter activity and/or the regulation. The present invention includes, f course, also the use of DNA fragments

containing such altered sequences of 5'flanking regions, and in particular DNA fragments can be mentioned which have been produced by recombining sequences of 5' flanking regions of any gene with 5' flanking regions of root nodule-specific genes provided the use of such DNA fragments subjects the expression of a desired gene product to the regulation characterised by the present invention.

It should be noted that the transformation of micro-organisms is carried out in a manner known per se, cf. e.g. Maniatis et al., (1982), Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Laboratory.

The transformation of plant cells, i.e. introduction of plasmid DNA into plant cells, is also carried out in a manner known per se, cf. Zambryski et al., (1983), EMBO J. 2, 2143-2150.

Cleavage with restriction endonucleases and digestion with other DNA modifying enzymes are well-known techniques and are carried out as recommended by the suppliers.

The _Agrobacterium rhizogenes_ 15834 rif^R was used as a typical representative of A. rhizogenes: see White et al., I.Bact., Vol. 141 (1980), 1134-1141.

Example 1

Sequence determination of 5' flanking regions of soybean leghemoglobin genes

From a soybean gene library the four soybean leg-

hemoglobin genes Lba, Lbc_1, Lbc_2, and Lbc_3 are provided as described by Jensen, E.Ø. et al., Nature Vol. 291, No. 3817, 677-679 (1981). The genetically stable in-bred invariable soybean species "Glycine max.var.Evans" was used as a starting material for the isolation of the DNA used for the construction of said gene library. The 5' flanking regions of the four soybean leghemoglobin genes are isolated, as described by Jensen, E.Ø., Ph D Thesis, Institut for Molekylær Biologi, Århus Universitet (1985), and the DNA sequences determined by the use of the dideoxy method as described by Sanger, F., J. Mol. Bio. 143, 161-178 (1980) and indicated in the sequence scheme.

Example 2

Construction of Lbc_3-5'-3'-CAT

The construction has been carried out in a sequence of process steps as described below:

a) Sub-cloning the Lbc_3 gene

The Lbc_3 gene was isolated on a 12Kb EcoRI restriction fragment from a soybean DNA library, which has been described by Wiborg et al., in Nucl. Acids Res. (1982) 10, 3487. A section of the fragment is shown at the top of the attached Scheme 2. This fragment was digested by the enzymes stated and then ligated to pBR322 as indicated at the Scheme. The resulting plasmids Lbc_3HH and Lbc_3HX were subsequently digested by PvuII and religated, which resulted in two plasmids called pLpHH and pLpHX.

b) Sub-cloning 5'flanking sequences from the Lbc_3 gene

For this purpose pLpHH was used as shown in the attached Scheme 3. This plasmid was opened by means of PvuII and treated with exonuclease Bal31. The reaction was stopped at various times and the shortened plasmids were ligated into fragments from pBR322. These fragments had been treated in advance as shown in Scheme 3, in such a manner that in one end they had a DNA sequence TTC ---
AAG ---.

After the ligation a digestion with EcoRI took place, and the fragments containing 5' flanking sequences were ligated into EcoRI digested pBR322. These plasmids were transformed into E. coli K803, and the plasmids in the transformants were tested by sequence analysis. A plasmid, p213 5'Lb, isolated from one of the transformants, contained a 5' flanking sequence terminating 7 bp before the Lb ATG start codon in such a manner that the sequence is as follows:

2Kb
-5' flanking --- AAAGTAGAATTC
Lbc_3 sequence

E.coli K803 is a typical representative of the E. coli K12 recipient strains.

c) Sub-cloning 3' flanking region of the Lbc_3 gene

For this purpose pLpHX was used which was digested by XhoII. The ends were partially filled out and excess single-stranded DNA was removed with S1 nuclease, as shown in the attached Scheme 4. The fragment shown was ligated into pBR322 which had been pretreated as shown in the Scheme. The construction was transformed into E. coli K803. One of the transformants contained a plasmid called Xho2a-3'Lb. As the XhoII recognition sequence is positioned immediately after the Lb stop codon, cf. Scheme 2, the plasmid contained about 900 bp of the 3' flanking region, and the sequence started with GAATTCTACAA---.

The construction of Lb promoter cassette

An EcoRI/SphI fragment from Xho2a-3'Lb was mixed with a BamHI/EcoRI fragment from p213-5'Lb. These two fragments were ligated via the BamHI/SphI cleavage sites into a pBR322 derivative where the EcoRI recognition sequence had been removed, cf. Scheme 4. The ligated plasmids were transformed into E. coli K803. A plasmid in one of the transformants contained the correct fragments, and it was called pEJLb 5'-3'-1.

Construction of the Lbc_3 5'3'-CAT gene

The CAT gene of pBR322 was isolated on several smaller restriction fragments, as shown in the attached Scheme 5. The 5' coding region was isolated as an AluI fragment which was subsequently ligated into pBR322, treated as stated in the Scheme. This

was transformed into E. coli K803. Several transformants contained the correct plasmid. One was taken out and called Alu11. The 3' coding region was isolated on a TaqI fragment. This fragment was treated with exonuclease Bal31, whereafter EcoRI linkers were added. Then followed a digestion with EcoRI and a ligation to EcoRI digested pBR322. The latter was transformed into E. coli K803 and the transformants were analysed. A plasmid, Taq 12, contained the 3' coding region of the CAT gene plus 23 bp 3' flanking sequences subsequently terminating in the following sequence CCCCGAATTC. Subsequently the following fragments were ligated together to EcoRI digested pEJLb5'-3'-1: EcoRI/PvuII fragment from AluI, PvuII/Ddel fragment from pBR322 and DdeI/EcoRI fragment from Taq 12. This ligation mixture was transformed into E. coli K803. Several transformants contained the correct plasmid. One was taken out and was called pEJLb 5'-3' CAT 15.

Example 3

a.

Cloning and integration of the soybean Lbc_3-5'-3'-CAT gene.

Two EcoRI fragments (No. 36 and No. 40) of the T_L-DNA region of A. rhizogenes 15834 pRi plasmid was used as "integration sites". Thus the Lbc_3-5'-3-CAT gene was subcloned (as 3,6 Kb BamHI/SalI fragment) into two vectors pAR1 and pAR22 carrying the ab ve EcoRI fragments. The resulting plasmids pAR29

and pAR30 were separately mobilized into _A. rhizogenes_ 15834 rif^R using a plasmid helper system; see E. van Haute et al. (1983), EMBO J. 3, 411-417. Neither pAR29 nor pAR30 can replicate in Agrobacterium. Therefore the selection by means of rifampicin 100 µg/ml and the plasmid markers spectinomycine 100 µg/ml, streptomycine 100 µg/ml or kanamycine 300 µg/ml will select _A. rhizogenes_ bacteria having integrated the plasmids via homologous recombination through the EcoRI fragments 36 or 40. The structure of the resulting T_L-DNA regions - transferred to the transformed plant lines L5-9 and L6-23 - has been indicated at the bottom of the attached Scheme 6. In this Scheme is furthermore for the L6-23 line shown the EcoRI and HindIII fragments carrying the Lbc_3-5'-3'-CAT gene and therefore hybridizing to radioactively labelled Lbc_3-5'-3'-CAT DNA used as a probe, cf. Example 4_a_.

_b._

Cloning and integration of the soybean Lbc_3 gene.

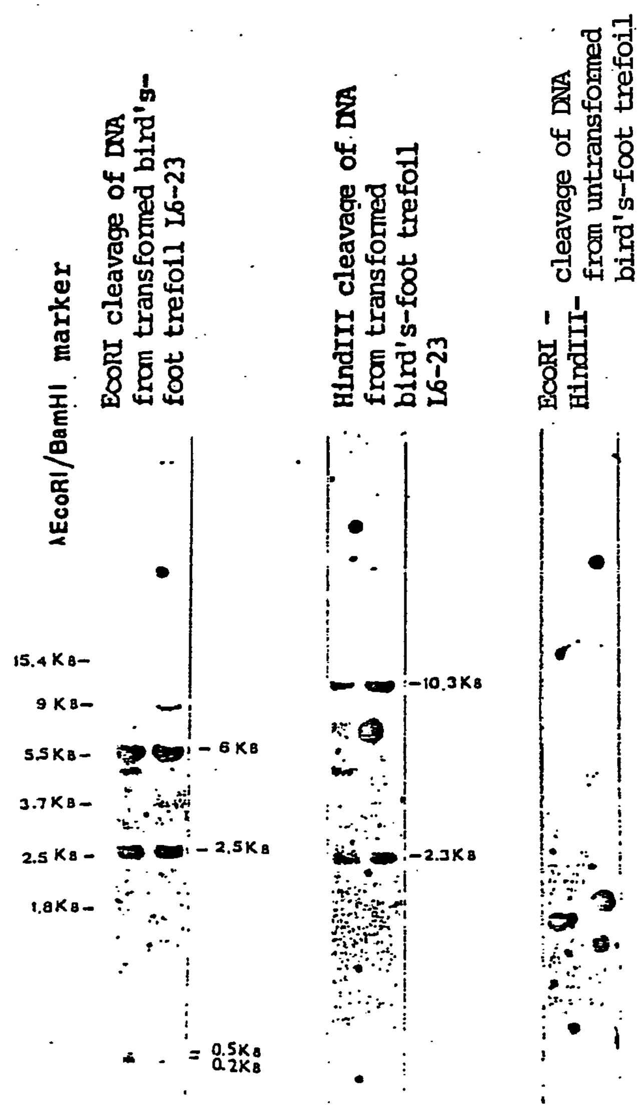
The EcoRI fragment No. 40 has here been used as "integration site". The Lbc_3 gene was therefore sub-cloned (as a 3,6 Kb BamHI fragment into the pAR1 vector and transferred into the T_L-DNA region as stated in a. The structure of the T_L-DNA region, transferred to the transformed plant line L8-35, has been shown at the bottom of the attached Scheme 7. This Scheme furthermore shows the EcoRI and HindIII fragments carrying the Lbc_3 gene and there-

fore hybridizing with radioactively labelled Lbc_3 DNA used as a probe, cf. Example 4<u>b</u>.

Example 4.

a.

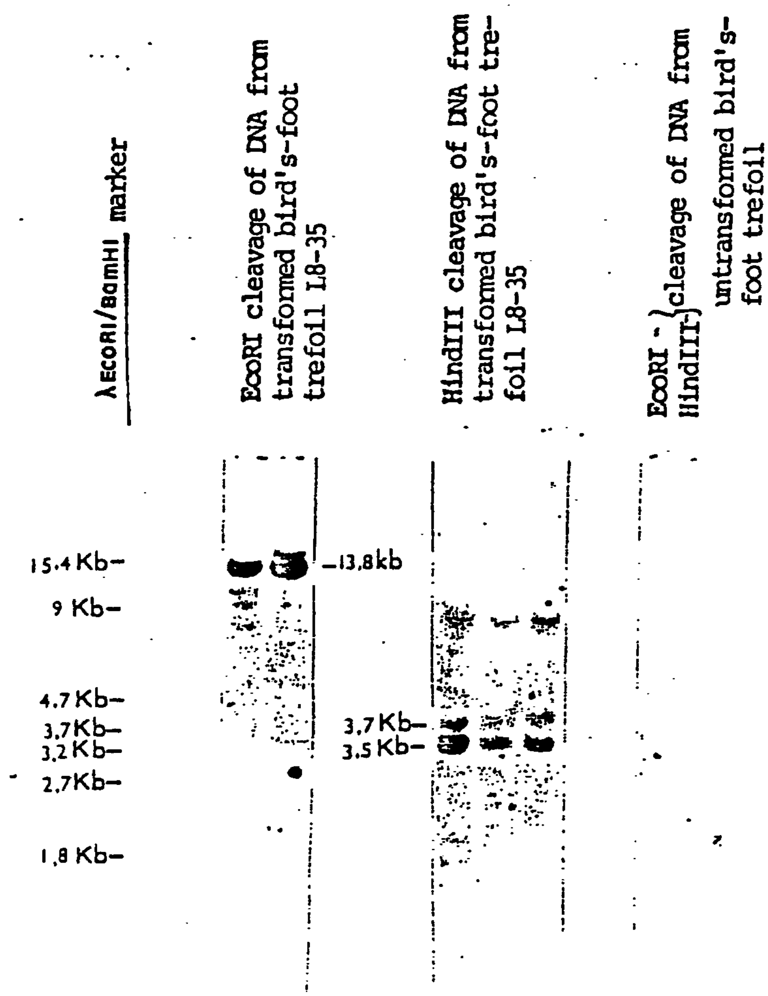
Demonstration of the soybean Lbc_3-5'-3'-CAT gene in transformed plants of bird's-foot trefoil.



DNA extracted from transformed lines (L6-23) or untransformed control plants and cleaved by the restriction enzymes EcoRI and HindIII was analyzed by Southern-hybridization. Radioactively labelled Lbc_3-5'-3'-CAT gene was used as a probe for demonstrating corresponding sequences in the transformed lines. The bands marked with numbers correspond to restriction fragments constituting parts of the Lbc_3-5'-3'-CAT gene as stated in the restriction map (Scheme 6) of Example 3a.

b.

Demonstration of the soybean Lbc_3 gene of transformed plants of bird's-foot trefoil.

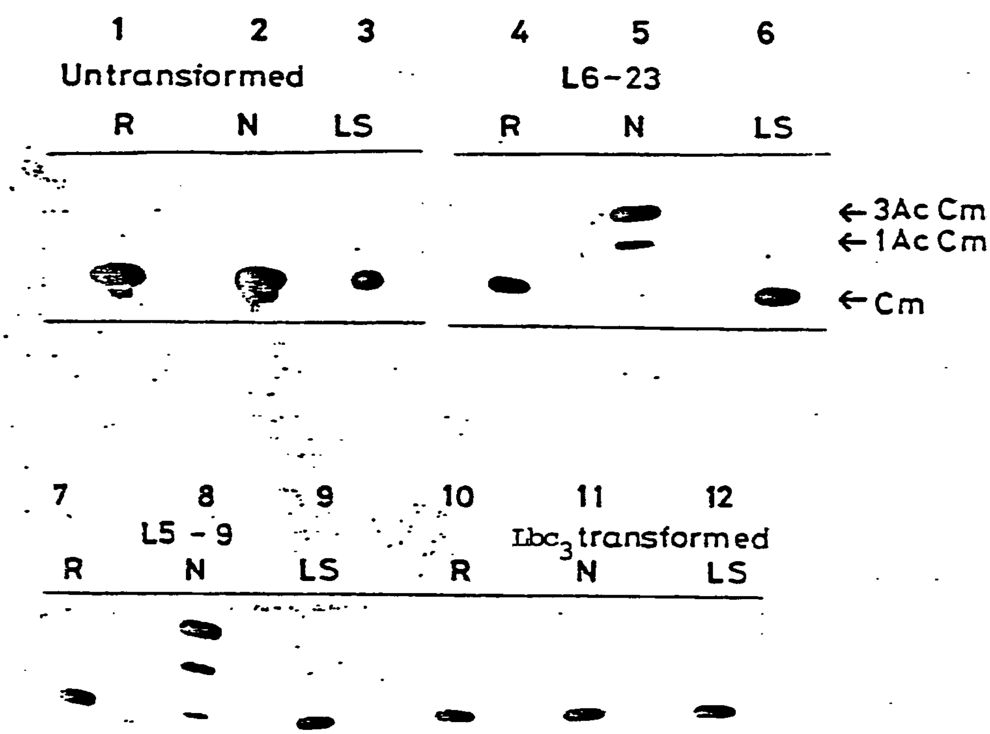


DNA extracted from transformed lines (L8-35) or untransformed control plants and cleaved by the restriction enzymes EcoRI and HindIII was analyzed by Southern-hybridization. Radioactive Lbc_3 gene was used as a probe for detecting corresponding sequences in the transformed lines. The bands marked with numbers correspond to restriction fragments constituting parts of the Lbc_3 gene as stated in the restriction map (Scheme 7) f Example 3b.

Example 5

a.

Expression of the Lbc_3-5'-3'-CAT gene in various tissues of bird's-foot trefoil.



The activity of the chloroamphenicol acetyl transferase (CAT) enzyme is measured as the amount of acetylated chloroamphenicol (AcCm) produced from ^{14}C-chloroamphenicol. In (a) the acetylated forms 1AcCm and 3AcCm appear, which have been separated from Cm through thin-layer chromatography in chloroform/methanol (95:5). The columns 1-3 show that no CAT activity occurs in root (R), nodule (N), as well as leaves + stem (LS) of untransformed plants of bird's-foot trefoil. The columns 4-6 and 7-9 show the CAT activity in corresponding tissues of Lbc_3-5'-3'-CAT transformed L6-23 and L5-9 plants. The conversion of chloroamphenicol in columns 5 and 8 shows the organ-specific expression of the Lbc_3-5'-3'-CAT gene in root nodules. The columns 10-12 show the lack of CAT activity in plants transformed with the Lbc_3 gene.

b.

Table

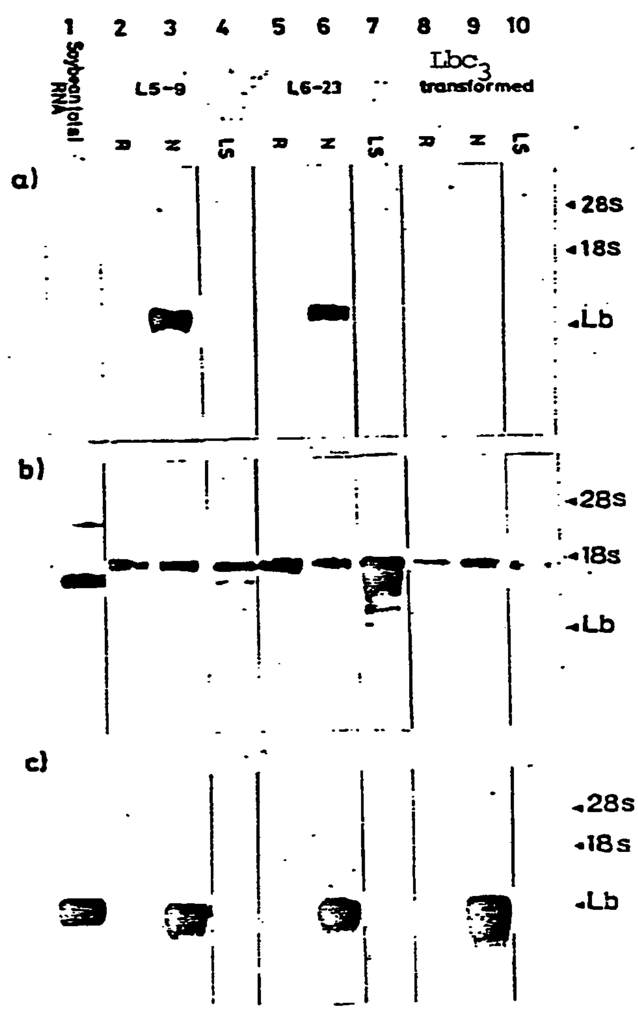
	L6-23 CAT activity	L5-9 CAT activity
Root	0	0
Nodule	68830 cpm/μg protein·h	154,000 cpm/μg protein·h
Leaves + Stem	0	0

In the Table (b) the CAT activity in Lbc_3-5'-3'-CAT transformed L5-9 and L6-23 plants has been stated as the amount of ^{14}C-chloroamphenicol converted into acetylated derivatives. The amount of radioactivity in the acetylated derivatives has been

counted by liquid scintillation and stated in cpm/μg protein · hour.

Example 6

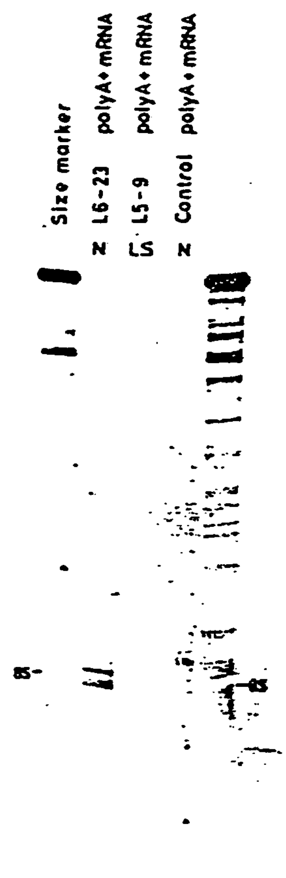
Transcription test (Northern analysis) on tissues of Lbc_3-5'-3'-CAT transformed and Lbc_3 transformed Lotus plant lines.



5 μg of total RNA extracted from root (R), nodule (N) or leaves + stem (LS) and separated in formaldehyde agarose gels were transferred onto nitrocellulose. Column 1 contains 5 μg of total RNA from 20-day-old soybean nodules as control plants. The columns 2-4 and 5-7 contain total RNA from root, nodule or leaves + stem, respectively, of the Lbc_3-5'-3'-CAT transformed lines L5-9 and L6-23. The columns 8-10 contain RNA from corresponding tissues of bird's-foot trefoil transformed by means of A. rhizogenes carrying the Lbc_3 gene in the T_L-DNA. In (a) radioactive DNA of the CAT coding sequence has been used as a probe for hybridization. The organ-specific transcription of the Lbc_3-5'-3'-CAT gene in root nodules from the L5-9 and L6-23 lines appears from columns 3 and 6. In (b) the transcript for the constitutive ubiquitine gene(s) is visualized using a cDNA probe for the human ubiquitine gene for the hybridization. In (c) the nodule-specific transcription of bird's-foot trefoil own leghemoglobin genes is shown. A cDNA probe of the Lba gene of soybean has been used for this hybridization.

Example 7

Determination of the transcription initiation site (CAP site) of the Lbc_3 promoter of soybean in transformed root nodules of bird's-foot trefoil.



—TATAAATAAGTATTTGGATGTGAAGTTGTTGCATAACT—/ /—AAATGGAG

83

The position of the "CAP site" was determined on the nucleotide level by means of primer extension. A synthetic oligonucleotide 5'CAACGGTGGTATATCCAGTG3' complementary to the nucleotides 15-34 in the coding sequence of the CAT gene was used as primer for the enzyme reverse transcriptase. As a result single-stranded cDNA was formed the length of which corresponds to the distance between the 5' end of the primer and the 5' end of the primed mRNA. A 83 nucleotide cDNA strand would be expected according to the knowledge of the transcription initiation site of soybean Lbc_3 gene. Columns 2, 3, and 4 from left to right show the produced DNA strands when the primer extension has been operated on $polyA^+$-purified mRNA from transformed root nodules of bird's-foot trefoil, transformed leaves + stem of bird's-foot trefoil, and untransformed root nodules of bird's-foot trefoil, respectively. The 85, 86, 87, 88, and 90 nucleotides long cDNA strand shown in column 2 proved correctly Lbc_3 promoter function in bird's-foot trefoil. The CAP sites corresponding to the cDNA sequences generated are indicated with asterisks (*) on the partial sequence of the Lbc_3 5'3'-CAT region given. In the sequence the TATA box of the Lbc_3 promoter and the corresponding translation initiation codon of the CAT coding sequence are underlined.

Example 8

Demonstration of the correct developmental control of the Lbc_3-5'-3'-CAT gene in transformed plants of bird's-foot trefoil (L6-23).

	Stage 1: No visible nodules	Stage 2: Emerging nodules	Stage 3: Distinct white nodules	Stage 4: Small pink nodules	Stage 5: Later stages of maturity
CAT activity in cpm/μg protein·hour	0	0	32.6	342.3	1255*
Nitrogenase activity nmol ethylene/μg protein · hour	0	O	0	O.5	2.7

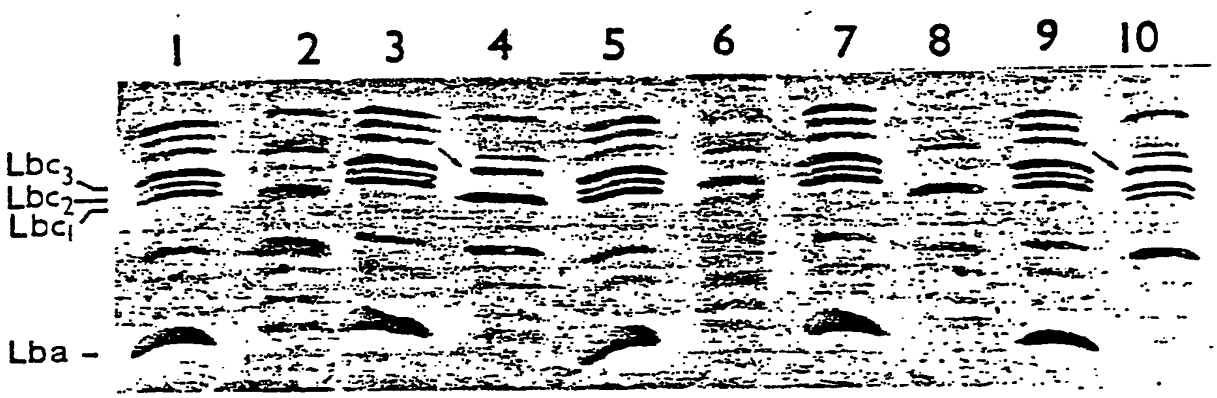
* Substrate limited reaction; actual activity about 68000 cpm/μg protein · hour.

Chloroamphenicol acetyl transferase and nitrogenase activity were measured on cut off pieces of root with nodules at the different developmental stages indicated. The CAT activity can be detected in the white distinct nodules whereas the nitrogenase activity did not appear until the small pink nodules have developed. The latter development corresponds to the development known from soybean control plants and described by Marcker et al. EMBO J. 1984, 3, 1691-95. The CAT activity was determined as in Example 5. The nitrog nase activity was measured

as acetylene reduction capacity of the nodules followed by gaschromatographic determination of ethylene.

Example 9

Demonstration of Lbc_3 protein in bird's-foot trefoil plants transformed with the soybean Lbc_3 gene.



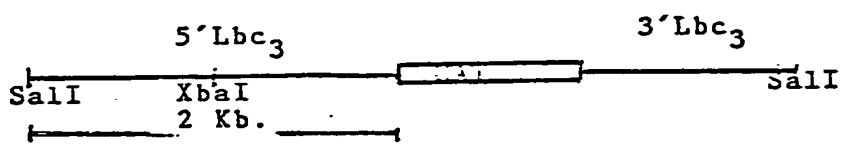
Proteins extracted from root nodules of Lbc_3 transformed (L8-35), Lbc_3-5'-3'-CAT transformed and nontransformed plants were separated by isolectric focussing at a pH gradient of 4 to 5. The columns 1, 3, 5, 7, and 9 show Lbc_1, Lbc_2, Lbc_3, and Lba proteins synthesized in soybean control root nodules. Column 2 shows proteins from root nodules of Lbc_3-5'-3'-CAT transformed L6-23-bird's-foot trefoil plants, whereas the columns 6 and 8 show proteins from nontransformed plants. The columns 4 and 10 show soybean Lbc_3 protein synthesized in root nod-

ules of bird's-foot trefoil plants (L8-35) transformed with the Lbc_3 gene. The Lbc_3 protein band is indicated by an arrow.

Example 10

Expression of the Lbc_3-5'-3'-CAT gene requires the 5' Lbc_3 promoter region.

The Lbc_3-5'-3'-CAT gene construction carries a 2 Kb 5' Lbc_3 promoter region. Stepwise removal of sequences from the 5' end of this region demonstrated that this promoter region is required for the characteristic expression of the Lbc_3-5'3'-CAT gene.



The Lbc_3-5'-3'-CAT gene construction was opened in the unique XbaI site shown above, and digested with the exonuclease Bal31. A SalI linker fragment was ligated onto the blunt ends generated and the shortened SalI fragments carrying the Lbc_3-5'-3'-CAT gene were transferred into L.corniculatus. The effect of removing promoter sequences was measured as CAT activity. End points of the deleted 5' region are given as the distance from the CAP site in nucleotides.

	CAT activity Cpm/µg protein/hrs.		
	Root	Nodule	Leaf
2000	0	80000	0
-950	0	10000	0
-474	0	3000	0
-230	0	3000	0
-78	0	0	0

The drastically reduced level of CAT activity expressed from the Lbc_3 promoter deleted to nucleotide -230 and the zero activity from the promoter deleted to nucleotide -78 demonstrates that the Lbc_3 promoter region is required for the root nodule specific expression of the Lbc_3-5'-3'-CAT gene.

<u>Example 11</u>

<u>Construction of the N23-CAT gene</u>.

The N23 gene was isolated from a soybean DNA library as described in the enclosed paper of Sandal, Bojsen and Marcker. The N23-CAT gene was constructed from the modified Lbc_3-5'-3'-CAT gene carried on plasmid pEJ5'-3'-CAT101 as described in the Applicant's copending application No. 86 11 4704.9 concerning "Expression of Genes in Yeast", and a 1 Kb. EcoRI, DdeI fragment containing the N23 5' promoter region. The position of the EcoRI and DdeI sites in the N23 promoter region is indicated on the DNA sequence shown below. The cloning procedure used is outlined

below. The disclosure of the papers of Sandal et al., the EP application, and the paper of Jensen et al., Nature 321 (12 June 1986), 669-674, including the references cited should be considered incorporated into the present description as a means to amend, illustrate, and clarify it.

The N23-CAT gene was transferred to plants by the same method as the Lbc_3-5'-3'-CAT gene.

Example 12

Organ-specific expression of the soybean N23-CAT gene in root nodules of L.corniculatus and Trifolium repens.

The activity of chloroamphenicol acetyl transferase (CAT) was measured as in example 5 and is given in cpm/μg protein/hrs.

Table a.

	CAT activity	
	N23-CAT transformed L.corniculatus	Untransformed L.corniculatus
Root nodule	86150	0
Root	0	0

Table b.

	CAT activity	
	N23-CAT transformed T.repens	Untransformed T.repens
Root nodule	148000	0
Root	0	0

Table (a) and b) shows the organ-specific expression of the N23-CAT gene in root nodules of L.corniculatus and T.repens. L.corniculatus was inoculated with Rhizobium loti, while T.repens was inoculated with Rhizobium trifolii.

In connection with the invention it has thus been proved that root nodule-specific genes can be expressed organ-specifically upon transfer to other plants, here Lotus corniculatus and Trifolium re-

pens. It has furthermore been proved that the 5' flanking regions comprising the promoter are controlled by the organ-specific regulatory mechanism as the organ-specific control of the Lbc_3-5'-3'-CAT gene in Lotus corniculatus took place at the transcription level. The Lbc_3-5'-3'-CAT gene transferred was thus only transcribed in root nodules of transformed plants and not in other organs such as roots, stems, and leaves.

The expression of the Lbc_3-5'-3'-CAT gene in root nodules of transformed plants also followed the developmental timing known from soybean root nodules. No CAT activity could be detected in roots or small white root nodules (Example 8). A low activity was present in the further developed white distinct nodules, whereas a high activity could be measured in the small pink nodules and mature nodules developed later on.

The organ-specific expression and the correct developmental expression of transferred root nodule-specific genes, here exemplified by the Lbc_3-5'-3'-CAT gene, allows as a particular use a functional expression of root nodule-specific genes also in other plants beyond leguminous plants. When all the root nodule-specific plant genes necessary for the formation of root nodules are transferred from a leguminous plant to a non-root-nodule-forming plant species, the correct organ-specific expression proved above allows production of functionally active, nitrogen-fixing root nodules on this plant upon infecti n by Rhizobium. In this manner these plants can grow without the supply of external

inorganic or organic nitrogen compounds. Root nodule-specific promoters, here exemplified by the Lbc_3 and N23 promoters, must be used in the present case for regulating the expression of the transferred genes.

According to the present invention a root nodule-specific promoter is used for expressing genes. The gene product or function of the gene product improves the function of the root nodule, e.g. by altering the oxygen transport, the metabolism, the nitrogen fixation or the nitrogen absorption.

Root nodules are thus used for the synthesis of biological products improving the plant per se or which can be extracted from the plant later on. A root nodule-specific promoter can be used for expressing a gene. The gene product or compound formed by said gene product constitute the desired product(s).

In connection with the present invention it has furthermore been proved that the soybean Lbc_3 leghemoglobin protein per se, i.e. the Lbc_3 gene product, is present in a high concentration in root nodules of bird's-foot trefoil plants expressing the Lbc_3 code sequence under the control of the Lbc_3 promoter. The latter has been proved by cloning the genomic Lbc_3 gene of the soybean into the integration vector pAR1, said genomic Lbc_3 gene containing the coding sequence, the intervening sequences, and the 5' and 3' flanking sequences. A 3.6 Kb BamHI fragment Lbc_3HH, cf. Example 2, was cloned into the pAR1 plasmid and transferred to

bird's-foot trefoil as stated previously.

The high level of Lbc_3 protein, cf. Example 9, found in transformed root nodules of bird's-foot trefoil and corresponding to the level in soybean root nodules proves an efficient transcription of the Lbc_3 promoter and an efficient processing and translation of Lbc_3mRNA in bird's-foot trefoil.

The high level of the CAT activity present in transformed root nodules is also a result of an efficient translation of mRNA formed from the chimeric Lbc_3 gene. The leader sequence on the Lbc_3 gene is decisive for the translation initiation and must determine the final translation efficiency. This efficiency is of importance for an efficient synthesis of gene products in plants or plant cells. An Lbc_3 or another leghemoglobin leader sequence can thus be used for increasing the final expression level of a predetermined plant promoter. The construction of a DNA fragment comprising a Lb leader sequence as first sequence and an arbitrary promoter as second sequence is a particular use of the invention when the construction is transferred and expressed in plants.

During nodule development around 30 different plant encoded polypeptides (nodulins) are specifically synthesized. Apart from the leghemoglobins, nodulins include nodule-specific forms of uricase (Bergmann et al (1983) EMBO. J. 2, 2333-2339), glutamine synthetase (Cullimore et al (1984) J.Mol. Appl. Genetics 2, 589-599) and sucrose synthase (Morell and C peland (1985) Plant. Physiol. 78,

149-154). The function of most nodulins are, however, at present unknown.

Many nodulin genes have nevertheless been isolated and characterised during the last five years. These include nodulins from several different legumes. Examples of such isolations and characterisations are widespread in the literature such as (Fuller et al (1983) Proc. Natl. Acad.Sci. 80, 2594-2598), (Sengupta-Gopalan et al (1986) Molec. Gen. Genet. 203, 410-420), (Bisseling et al (1985) in Proceedings of the 6th Int. symp. on Nitrogen Fixation, Martinus Nijhoff Publishers pp 53-59.), and (Gebhardt et al (1986) EMBO.J.5, 1429-1435). All of these genes contain nodule-specific regulatory sequences. Such sequences and in fact entire 5' flanking regions and 3' flanking regions can furthermore be synthesized by automated oligonucleotide synthesis knowing the DNA sequences for the Lbc_3 and N23 genes given in this description. Entire nodule-specific genes can also be isolated with known recombinant techniques as described in the above papers and by (Maniatis et al (1982) Molecular cloning. A Laboratory Manual, Cold Spring Harbour Laboratory, New York).

The described method to obtain nodule-specific expression of genes can thus be reconstructed and performed according to the invention by any one skilled in the art of molecular genetics.

The method to obtain nodule-specific expression is not dependent on the <u>A. rhizogenes</u> plant transformation described. Any other plant transformation

system e.g. A. tumefaciens systems, direct gene transfer or microinjection can equally be applied.

The A. rhizogenes system has been used and characterised by a number of scientific groups and is thus well-known from the literature. The characteristics of the system is described in:

Willmitzer et al. (1982), Molec.Gen. Genet. 186, 16-22,

Chilton et al. (1982), Nature 295, 432-434,

Simpson et al. (1986), Plant.Molec.Biol. 6, 493-415,

Tepfer D. (1983), Molecular Genetics of the Bacteria - Plant interaction,

Springer Verlag, Berlin Heidelberg pp 248-258,

White and Nester (1980), J.Bact. 144, 710-720,

Jaynes and Strobel (1981), Int.Rev. of Cytol. Sup. 13, 105-125,

White and Nester (1980), J. Bact. 141, 1134-1141,

Pomponi et al. (1983), Plasmid 10, 119-129, and

Slightom et al. (1986), J. Biol. Chem. 261, 108-121.

The latter two publications describe the restriction map and nucleotide sequence of the *A. rhizogenes* T_L-DNA segment used in the transformation system described here. With this information it is possible to anybody skilled in molecular genetics to use and reconstruct the "intermediate vectors" and the *A. rhizogenes* strains described here.

Claims:

1. A method of expressing genes in plants, parts of plants, and plant cell cultures by introducing into a cell thereof a recombinant DNA segment containing both the gene to be expressed and a 5' flanking region comprising a promoter sequence, and optionally a 3' flanking region, and culturing of the transformed cells in a growth medium, c h a r a c t e r i s e d by using as the recombinant DNA segment a DNA fragment comprising an inducible plant promoter (as defined) from root nodule-specific genes.

2. A method as claimed in claim 1, c h a r a c t e r i s e d by using a DNA fragment comprising an inducible plant promoter (as defined) and being identical with, derived from or comprising 5' flanking regions of root nodule-specific genes.

3. A method as claimed in claim 2, c h a r a c t e r i s e d by using a DNA fragment comprising an inducible plant promoter (as defined) and being identical with, derived from or comprising 5' flanking regions of root nodule-specific genes, said DNA fragment causing an expression of a gene which is induced in root nodules at specific stages of development and as a step of the symbiosis, whereby nitrogen fixation occurs.

4. A method as claimed in claims 1-3 for the expression of root nodule-specific genes, c h a r a c t e r i s e d by using a DNA fragment c mprising an inducible plant promoter (as defined)

from root nodule-specific genes.

5. A method as claimed in claims 1-3 for the expression of genes in leguminous plants, parts of leguminous plants, and leguminous plant cell cultures, c h a r a c t e r i s e d by using a DNA fragment comprising an inducible plant promoter (as defined) from root nodule-specific genes.

6. A method as claimed in claims 1-5, c h a r a c t e r i s e d by the DNA fragment comprising the inducible plant promoter and being identical with, derived from or comprising 5′ flanking regions of leghemoglobin genes.

7. A method as claimed in claim 6, c h a r a c t e r i s e d by the DNA fragment comprising the inducible plant promoter and being identical with, derived from or comprising 5′ flanking regions of soybean leghemoglobin genes.

8. A method as claimed in claim 7, c h a r a c t e r i s e d by the DNA fragment comprising the inducible plant promoter and being identical with, derived from or comprising 5′ flanking regions of the Lba gene with the sequence

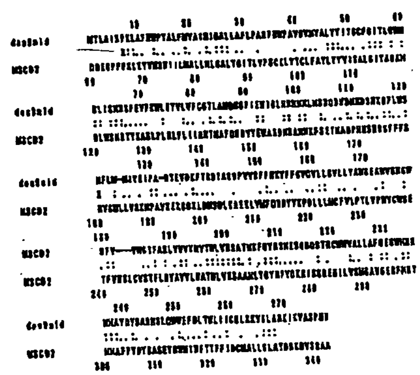
(54) Title : GENE FOR FATTY ACID DESATURASE, VECTOR CONTAINING SAID GENE, PLANT CONTAINING SAID GENE TRANSFERRED THEREINTO, AND PROCESS FOR CREATING SAID PLANT

(54) 発明の名称　脂肪酸の不飽和化酵素遺伝子、当該遺伝子を含むベクター、当該遺伝子が導入された植物及びその作出方法



(57) Abstract

A gene coding for a protein having the activity of desaturating the Δ9-position of a fatty acid bound to a lipid; a vector containing a polynucleotide containing the whole or part f said gene; a plant cell containing, transferred thereinto, a polynucleotide containing the whole or part of a gene coding for a protein having the activity of desaturating the Δ9-position of a fatty acid bound to a lipid; a process for creating a plant which comprises differentiating said plant cells and regenerating the plant body; and a plant containing, transferred thereinto, a polynucleotide c ntaining the whole or part of a gene coding for protein having the activity of desaturating the Δ9-position of a fatty acid bound to a lipid.

（５７）要約

脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質をコードする遺伝子；当該遺伝子又は当該遺伝子の一部を含むポリヌクレオチドを含むベクター；脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質をコードする遺伝子又は当該遺伝子の一部を含むポリヌクレオチドが導入された植物細胞；前記植物細胞を分化させて植物体を再生させることを特徴とする植物の作出方法；および、脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質をコードする遺伝子又は当該遺伝子の一部を含むポリヌクレオチドが導入された植物。

明 細 書

脂肪酸の不飽和化酵素遺伝子、当該遺伝子を含むベクター、当該遺伝子が導入された植物及びその作出方法

技術分野

本発明は、脂質に結合した脂肪酸のΔ9位を不飽和化する活性を有するタンパク質（以下、Δ9位不飽和化酵素という）をコードする遺伝子、当該遺伝子を含むベクター、当該遺伝子が導入された植物およびその作出方法に関するものである。

背景技術

生物の生体膜を構成する脂質である膜脂質は外界温度の低下に伴って、液晶状態から固体状態へと変化（相分離）する。そして、かかる相分離に伴い生体膜の性質が変化する。すなわち、膜脂質が固体状態では物質透過の選択性がなくなるため、生体膜が本来の機能を果たせなくなり、その結果細胞に傷害（低温傷害）が生ずると考えられている。

液晶状態から固体状態あるいはその逆に変化する温度である膜脂質の相転移温度は、主に脂質に結合している脂肪酸アシル基の不飽和度（炭素鎖中の二重結合の数）によって決定付けられる。すなわち、結合している脂肪酸アシル基が二つとも飽和脂肪酸である場合、この脂質分子種の相転移温度は室温よりも高いが、結合した脂肪酸アシル基に二重結合を少なくとも1個持つような脂質分子種の相転移温度は、ほぼ0℃以下である（Santaren, J.F.et al., Biochim. Biophys. Acta, 687:231, 1982）。

なお、一般に脂肪酸の二重結合の位置は、そのカルボキシル基末端から二重結合のある炭素までの炭素数をΔ（デルタ）に続いて示す。また、二重結合の総数は全炭素数の後にコロンに続いて記載する。例えば、リノール酸は18:2Δ9,12と記述され、その構造は

$$CH_3(CH_2)_4\ CH=CHCH_2\ CH=CH\ (CH_2)_7\ COOH$$

である。また、二重結合の位置をω（オメガ）に続いて記載する場合があるが、

これは脂肪酸のメチル基末端から二重結合のある炭素までの炭素数を示している。

高等植物の膜脂質の中で、飽和分子種が比較的多いのはホスファチジルグリセロール（ＰＧ）のみであり、植物の低温傷害の起因がＰＧの相転移によること（Murata, N. et al., Plant Cell Physiol., 23:1071, 1982; Roughan, P. G., Plant Physiol., 77:740, 1985 ）、またＰＧの分子種組成が葉緑体に存在するグリセロール－３－リン酸アシルトランスフェラーゼ（以下ATase）の基質選択性によって決められていること（Frentzen, M. et al., Eur. J. Biochem., 129:629, 1983; Murata, N., Plant Cell Physiol., 24:81, 1983; Frentzen, M. et al., Plant Cell Physiol., 28:1195, 1988）が強く示唆されていた。

これらの仮定に基づき西澤らは、低温に強い植物のシロイヌナズナから取得したATase遺伝子をタバコに導入・発現することによりＰＧの飽和分子種含量を下げ、タバコを野生株よりも低温に対して強くすることができることを示した（ＰＣＴ特許出願：PCT/JP92/00024, 1992）。しかし、ATaseは元の植物中にも存在し、かりに外来のATaseを植物中で大量発現させたとしても、内在性のATaseと競合しあうことは避けられず、外来のATaseの効果が希釈される可能性は否めない。例えば、作成した形質転換タバコのうちシロイヌナズナのATaseを最も大量に発現しているクローンの葉のＰＧの飽和分子種含量は約28％でありタバコ野生株よりも約８％少ないが、シロイヌナズナ野生株よりも約８％多かった（ＰＣＴ特許出願：PCT/JP92/00024, 1992）。

さらに、一般にプラスチドで作られるアシル-ACP は主に16:0-ACPと18:1-ACPであり、またそれらの割合はほぼ等量であると考えられているが、組織によっては16:0-ACPや18:0-ACPの割合が18:1-ACPより高いことも考えられる（Toriyama, S. et al., Plant Cell Physiol., 29:615, 1988）。このような組織では外来のATaseによって飽和分子種含量を充分に減少させることが困難であるとも考えられる。

ところで、光合成細菌のシアノバクテリア（ラン藻）の膜脂質の組成は、高等植物の葉緑体を構成している膜系の脂質組成と類似している（Murata, N. et al., in“The Biochemistry of Plants”, Academic Press, 1987）。またラン藻では、膜脂質に結合した脂肪酸の不飽和度は、脂質に結合した脂肪酸を不飽和化する酵素によって制御されている。そして、脂質に結合した脂肪酸に二重結合を１つし

か入れられないAnacystis nidulans（別名 Synechococcus PCC 7942)は低温感受性であるが（Ono,T.et al.,Plant Physiol.,67:176,1981)、２つ以上入れられるSynechocystis PCC6803 は低温耐性であることが知られていた（Wada,H.et al.,Plant Cell Physiol.,30:971,1989）。

また、ラン藻における脂肪酸の不飽和化酵素は、すべて脂質を基質とし、脂質に結合した脂肪酸に二重結合を導入する。従って、ラン藻は16:0/16:0-および18: 0/16:0- の飽和分子種からなる膜脂質のＰＧ、ＳＱＤＧ、ＭＧＤＧおよびＤＧＤＧの脂肪酸にcis-型の二重結合を導入することが可能である（Murata,N.et al.,in "The Biochemistry of Plants",Academic Press, 1987）。かかる点は脂肪酸不飽和化酵素として、ステアロイル-ACP（18:0-ACP）のΔ９位に二重結合を導入する酵素を有し、一旦16:0/16:0-（および、わずかに存在する18:0/16:0-）の飽和分子種からなるＰＧおよびＳＱＤＧが合成されると、それらの脂肪酸に決してcis-型の二重結合を導入しない高等植物と大きく異なる点である。

現在、Synechocystis PCC6803 のΔ12位不飽和化酵素遺伝子をAnacystis nidulansに導入・発現させることにより本来Anacystis nidulansには存在しない16:2Δ9,12および18:2Δ9,12を生産させることが可能であり、結果として本来低温感受性であるAnacystis nidulansを低温耐性へと転換可能であることが示されている（Wada,H.et al.,Nature,347:200,1990）。

なお、これまでにラン藻の不飽和化酵素のうちΔ６位（Reddy,A.S.et al.,Plant Mol.Biol.,27:293,1993）およびΔ12位（Wada,H.et al.,Nature,347:200,1990)不飽和化酵素の遺伝子が取得されている。しかし、Δ９位に二重結合が導入されていなければ、Δ６位およびΔ12位不飽和化酵素は、それぞれΔ６位とΔ12位を不飽和化することはできない。また、Δ９位とΔ12位がともに不飽和化されていなければΔ15位不飽和化酵素はΔ15位を不飽和化することはできない。従って、脂肪酸のΔ９位を不飽和化する酵素の遺伝子を高等植物に導入し発現させれば、高等植物における飽和分子種含量を低下させ、その結果として該高等植物を低温耐性にすることができるはずである。しかしながら、現在まで、脂肪酸のΔ９位を不飽和化する酵素の遺伝子は得られていなかった。

従って、本発明は、脂肪酸のΔ９位を不飽和化する酵素の遺伝子およびその一

部を含むポリヌクレオチドを提供することを目的とする。

また、本発明は、脂肪酸のΔ９位を不飽和化する酵素の遺伝子またはその一部を含むポリヌクレオチドを含むベクターを提供することも目的とする。

さらに、本発明は、脂肪酸のΔ９位を不飽和化する酵素の遺伝子またはその一部を含むポリヌクレオチドが導入された植物細胞および植物を提供することも目的とする。

発明の開示

上記目的を達成するため、本発明者は、Anacystis 属に属するラン藻のゲノムＤＮＡからΔ９位不飽和化酵素をコードする遺伝子をクローニングし、該遺伝子を組み込んだベクターＤＮＡを得た後、該ベクターＤＮＡで植物細胞を形質転換し、これを分化させて植物体を再生させることにより、植物に低温耐性を付与することに成功し、本発明を完成させるに至った。すなわち、本発明は、以下の事項を要旨とするものである。

(1) 脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質をコードする遺伝子。

(2) 脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質が実質的に配列番号４に記載されたアミノ酸配列を有するものである(1)に記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチド。

(3) 脂質に結合した脂肪酸のΔ９位を不飽和化する活性を有するタンパク質をコードする遺伝子が配列番号３に記載の塩基配列を含むＤＮＡ鎖である(1)に記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチド。

(4) (1)乃至(3)のいずれかに記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドを含むベクター。

(5) (1)乃至(3)のいずれかに記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドが導入された植物細胞。

(6) (5)に記載の植物細胞を分化させて植物体を再生させることを特徴とする植物の作出方法。

(7) (1)乃至(3)のいずれかに記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドレ

オチドが導入された植物。

図面の簡単な説明

第１図は、des 9 var 断片がコードするアミノ酸配列とマウスのステアロイル－ＣｏＡ不飽和化酵素（ＭＳＣＤ２）のアミノ酸配列の比較を示す。図中で両者が同一のアミノ酸の場合は：、性質が類似したアミノ酸の場合は・を付け比較した。Ｘは、その間での相同性が高い範囲を示す。

第２図は、des 9 var 断片をプローブとして、Anacystis nidulans のゲノムＤＮＡをサザン分析したオートラジオグラムを示す電気泳動写真である。

第３図は、λ５、λ15およびｐ15Ｘのインサート DＮＡ断片の相互関係を示す。太い矢印はタンパク質をコードしている部分と方向を、細い矢印はシーケンスを決定した部位とその方向を示す。

第４図は、des 9 nidとマウスのステアロイル－ＣｏＡ不飽和化酵素（ＭＳＣＤ２）のアミノ酸配列の比較を示す。アミノ酸配列の比較は第１図と同様にして行った。

第５図は、植物体レベルでの形質転換タバコに対する低温処理の影響を示す生物の形態の写真である。左は不飽和化酵素遺伝子を導入したタバコを低温処理した結果を、右は対照としてpBI121を導入したタバコを低温処理した結果を示す。

発明の実施するための最良の形態

本発明にいう、Δ９位不飽和化酵素は、上記「従来の技術」等に記載したごとく本来ラン藻に存在する酵素である。Δ９位不飽和化酵素の化学構造は、マウス（Kaestner, K. H. et al., J. Biol. Chem., 264:14755, 1989)、ラット（Mihara, K., J. Biochem., 108:1022, 1990）及び酵母（Stukey, J. E. et al., J. Biol. Chem., 265:20144, 1990 ）のステアロイル－ＣｏＡ不飽和化酵素の化学構造と局所的に類似しているが全体的には大きく異なる。また既知のラン藻の脂質に結合した脂肪酸のΔ６位およびΔ12位の不飽和化酵素及び高等植物の脂質に結合した脂肪酸のω３位の不飽和化酵素（Yadav, N. S. et al., Plant Physiol., 103:467, 1993）の化学構造とは全く類似していない。本発明遺伝子を

天然素材から製造する場合は、ラン藻を原材料として使用するとよい。ここで用いられるラン藻は特に限定されず、例えばAnacystis属、Synechocystis属、Anabaena属等に属するラン藻を挙げることができる。なお、以下の理由により、高等植物の飽和分子種を不飽和化するためにはAnacystis型（Murata,N. et al., Plant Cell Physiol., 33: 933, 1992 。この文献で言うグループ１型のラン藻）のΔ９位不飽和化酵素の方がAnabaena型及びSynechocystis型の酵素よりも好ましい。

すなわち、Synechocystis PCC6803 とAnabaena variabilisでは、その膜脂質のほとんどがsn-1とsn-2にそれぞれ炭素数18の脂肪酸（Ｃ18）と炭素数16の脂肪酸（Ｃ16）を結合している（Sato,N. et al., Biochim. Biophys. Acta, 710: 279, 1982; Wada,H. et al., Plant Cell Physiol., 30:971, 1989 ）のに対して、Anacystis nidulansではほとんどがsn-1とsn-2ともにＣ16を結合している（Bishop, D. G. et al., Plant Cell Physiol., 27:1593, 1986）。従って、AnabaenaとSynechocystisのΔ９位不飽和化酵素は主に18:0/16:0-の分子種を基質としてsn-1の18:0を18:1Δ９に不飽和化する活性を有すると思われる。これに対してAnacystisのΔ９位不飽和化酵素は主に16:0/16:0-の分子種を基質としてsn-1の16:0を16:1Δ９に不飽和化する活性を有すると思われる。さらに、高等植物に多く見られる飽和分子種が16:0/16:0-であることから、高等植物の飽和分子種を不飽和化するためにはAnacystis型のΔ９位不飽和化酵素のほうがAnabaenaおよびSynechocystis型の酵素より適切である。

本発明遺伝子は後述する実施例に示すように、実質的に配列番号４に記載されたアミノ酸配列を有するΔ９位不飽和化酵素をコードするものを含み、縮重コドンにおいてのみ異なっていて同一のポリペプチドをコードすることのできる縮重異性体を含むものである。本発明遺伝子は、主にＤＮＡ鎖としての具体的形態を有する。なお、「実質的に配列番号４に記載されたアミノ酸配列」とは、配列番号４に記載されたアミノ酸配列に加えて、Δ９位不飽和化酵素活性を有するかぎり、配列番号４に記載されたアミノ酸配列の一部に欠失、置換、付加などがあってもよいアミノ酸配列を含むものである。

本発明遺伝子は、上記ラン藻細胞から通常公知の手法を用いて製造することが

できる。

すなわち、ラン藻細胞を培養して集積し、当該ラン藻細胞からエタノール沈澱法等の通常公知の手法によりゲノムＤＮＡを調製し、当該ゲノムＤＮＡを基にした遺伝子ライブラリーを調製し、当該ライブラリーより所望の遺伝子を含むクローンを選抜し、これを増幅することで製造することが可能である。

ここで用いる遺伝子ライブラリー作成用ベクターとしては、当該ベクターとして通常用いられるものを挙げることができる。具体的には、λDASH II (Stratagene)等のファージ；pWE15 (Stratagene)等のコスミド；pBluescript II(Stratagene)等のファージミド等を挙げることができる。上記ベクターへの具体的な遺伝子導入方法は、それぞれのベクターに応じた通常公知の方法を用いることができる。

このようにして調製した遺伝子ライブラリーから本発明遺伝子が導入されたクローンを選抜する。

当該選抜方法としては通常公知の選抜方法、例えば抗体によるプラークハイブリダイゼーション法若しくはコロニーハイブリダイゼーション法等の免疫学的方法又はヌクレオチドプローブによるプラークハイブリダイゼーション法若しくはコロニーハイブリダイゼーション法等を用いることができる。なお、上記ヌクレオチドプローブの選択基準として、本発明遺伝子に類似すると推測される塩基配列の一部（例えば、第１図のMSCD2のアミノ酸配列番号260から295の一部を塩基配列に読みかえたもの）をプローブとして用いるのが好ましい。

このようにして選抜したクローンにおける本発明遺伝子の塩基配列の決定及び確認は、通常公知の方法を用いて行うことができる。例えば、マキサムーギルバート法（Maxam-Gilbert, Methods Enzymol., 65:499, 1980)やM13 ファージを用いるジデオキシヌクレオチド鎖終結法(Messing, J. et al., Gene, 19:269, 1982）等により行うことができる。

なお、Δ９位不飽和化酵素が実際に発現しているか否かの確認は例えば、和田らの方法（J. Bacteriol., 175:6056, 1993 ）に従って行うことができる。

上記のようにして塩基配列が決定された本発明遺伝子は、通常公知の手段、例えばホスファイト法を用いた市販のＤＮＡシンセサイザーで合成することも可能

である。

本発明遺伝子又は本発明遺伝子の一部を含みΔ9位不飽和化活性を有するポリペプチドをコードするポリヌクレオチドを上記クローンから分離し、これを植物体への遺伝子導入用ベクターに組み込み、このベクターを植物細胞へ導入し、Δ9位不飽和化酵素を植物体中で発現させることにより、所望の植物に低温耐性を付与することができる。

なお、上記の遺伝子導入が可能な植物の種類には特に制限はない。

ここでいう遺伝子導入用ベクターは、Δ9位不飽和化酵素遺伝子が植物体中で安定に発現しうるように構成されることが必要である。具体的には、プロモーター、翻訳調節領域をコードするＤＮＡ鎖、葉緑体への転移ペプチドをコードするＤＮＡ鎖、本発明遺伝子又は本発明遺伝子の一部を含みΔ9位不飽和化活性を有するポリペプチドをコードするポリヌクレオチド、翻訳終止コドンをコードするＤＮＡ鎖及びターミネーターが適切な位置関係で組み込まれていることが必要である。なお、本発明遺伝子以外の遺伝子導入用ベクターの構成要素としては通常公知のものを用いることができる。上記葉緑体への転移ペプチドをコードするＤＮＡ鎖としては、例えばエンドウのリブロース－1，5－二リン酸カルボキシラーゼの小サブユニット遺伝子を当該転移ペプチドをコードするＤＮＡ鎖として好適に用いることができる。プロモーターとしては、例えばカリフラワーモザイクウイルスの35Ｓプロモーターを、またターミネーターとしては、例えばノパリン合成酵素のターミネーターを用いることができる。

植物細胞への遺伝子導入方法としては、通常公知の方法、例えば「"Plant genetic transformation and gene expression; a laboratory manual", Draper, J. et al. eds., Blackwell Scientific Publications, 1988」記載の方法を用いて行うことができる。その例としては、生物的方法であるウィルスを用いる方法、アグロバクテリウムを用いる方法など、物理・化学的方法であるエレクトロポレーション法、ポリエチレングリコール法、マイクロインジェクションなどが挙げられる。これらのうち、タバコを初めとする双子葉植物に対しては、安定な形質転換を確実に行える点から、アグロバクテリウムを用いる方法が好ましい。アグロバクテリウムを用いる方法には、野生型腫瘍プラスミドを用いる中間ベクター

法(Nature, 287 (1980), p.654; Cell, 32 (1983) p.1033; EMBO J., 3 (1984) P.1525)、T－DNA上の腫瘍形成遺伝子領域を欠損させたベクターを利用する中間ベクター法(EMBO J., 2 (1983) P.2143; Bio/Technology, 3 (1985) p.629)、バイナリーベクター法(Bio/Technology, 1 (1983) p.262; Nature, 303 (1983) p.179; Nucl. Acids Res., 12 (1984) p.8711)などがあり、これらのいずれの方法を用いてもよい。アグロバクテリウムを植物に感染させる方法としては、培養細胞への直接接種法、プロトプラスト共存培養法、リーフディスク法等が挙げられるが、直接かつ容易に多数の形質転換植物体を作成することができるという点から、リーフディスク法を使用することが好ましい。

さらに、植物体を再分化させるには、MS-HF培地等の公知の培地に選択用の抗生物質や植物生長ホルモン等を添加した培地で培養すればよい。発根した幼植物体を土壌に移植して栽培すれば、完全な植物体にまで成長させることができる。

完全な植物体にまで成長させた形質転換植物が低温耐性を有しているか否かについては、以下のようにして検討することができる。

低温傷害を受けない温度（例えば２５℃）で検定植物を栽培した後、一時的に（例えば一週間）低温下（例えば４℃）で栽培し、植物への傷害、例えば葉のクロロシスや稔性の低下を測定すること、あるいは、低温下での生長量を対照植物と比較することにより検討できる。

以下実施例をあげて本発明を詳細に説明するが、本発明はこれらの実施例によって限定されるものではない。

〔実施例１〕Anabaena variabilisのΔ12位不飽和化酵素遺伝子（desA）の上流に隣接してあるオープンリーディングフレームのＤＮＡ断片のクローニング

Anabaena variabilis ＩＡＭ Ｍ－３（東京大学分子細胞生物学研究所より分譲）を、約100mlのＢＧ－11培地（"Plant Molecular Biology", Shaw, C.H. ed., p.279, IRL PRESS, 1988）で培養した。25℃、1,000luxの蛍光灯下で毎分120回振とうし、充分菌を生育させた。培養液を室温で5,000gで10分間遠心分離することにより菌体を沈殿物として回収した。

ゲノムＤＮＡを調製するため、菌体を50mlのＡ液（50mM Tris-HCl, 1mM EDTA, pH8.0）に懸濁して洗浄し、遠心分離することにより菌体を沈殿物として回収した。次に、15mlのＢ液（50mM Tris-HCl, 20mM EDTA, 50mM NaCl, 0.25 M sucrose, pH8.0）に懸濁し、Ｂ液で溶解した40mgのリゾチーム（Sigma）を加え37℃で１時間振とうした。次にプロテナーゼＫを15mgとＳＤＳを終濃度で１％になるように加え37℃で１晩振とうした。その後、$NaClO_4$を終濃度で１Ｍになるように加え、さらに20mlのクロロホルム／イソアミルアルコール（24:1）を加えて10分間振とうした後、遠心分離により水層を回収した。クロロホルム／イソアミルアルコール（24: 1)により再抽出した後、水層に50mlのエタノールを加え、ゲノムＤＮＡ調製物をガラス棒に巻き付けて回収した。このＤＮＡ調製物を20mlのＡ液に溶かし、NaClを終濃度で0.1Mにし、さらにRNaseを終濃度で50mg/mlになるように加え、37℃で１時間インキュベートした。次に、Ａ液で飽和した等量のフェノールで２回抽出した後、水層中のゲノムＤＮＡをエタノールを加えることにより沈殿物として回収し、70％エタノールで洗浄後、１mlのＡ液に溶かしAnabaena variabilis のゲノムＤＮＡ溶液とした。

坂本らはAnabaena variabilis 由来の膜脂質に結合した脂肪酸のΔ12位不飽和化酵素遺伝子のクローニングについて発表（1993年日本植物生理学会年会、講演要旨集、No. 3aF04）した際、Δ12位不飽和化酵素遺伝子の上流に隣接してオープンリーディングフレーム（ＯＲＦ）が存在し、これが不飽和化酵素と何らかの関係を有する可能性を報告したが、その機能は同定されていなかった。本発明者らはそのＯＲＦおよび機能に関心をもち、そのＯＲＦのＤＮＡ鎖中の３箇所の塩基配列に着目して、４本のプライマー（配列番号５～配列番号８）を合成し、Anabaena variabilisのゲノムＤＮＡを鋳型としてＰＣＲを行なった。

上記４本のプライマーのうち、配列番号５と６に示された塩基配列を有するプライマーがセンス鎖、配列番号７と８に示された塩基配列を有するプライマーがアンチセンス鎖をコードし、配列番号６と７に示された塩基配列は同一のアミノ酸配列に由来している。センス鎖およびアンチセンス鎖からそれぞれ任意に１種類ずつのプライマーを選び、計４種類のプライマーの組み合わせでＰＣＲを行なった。反応は、100μlの反応液中にプライマーを各20μM、Anabaena

variabilisのゲノムＤＮＡを１μg入れ、GeneAmp PCR Kit（宝酒造）を用いて行なった。反応の温度制御は、95℃（１分）、45℃（１分）、72℃（２分）を１サイクルとして35サイクル行なった。但し、１サイクル目の95℃は３分間とした。反応終了後、反応液10μlを２％アガロースゲルで電気泳動して合成されたＤＮＡを分離し分析した。その結果、配列番号６と８に示された塩基配列を有するプライマーの組み合わせで合成されたＤＮＡ中に、予想される大きさ（約190bp）のＤＮＡ断片が主要なバンドとして検出された。このＤＮＡ（以下、des 9 var という）断片の両末端をKlenowフラグメントで平滑化した後、プラスミドpTZ18R（Pharmacia)のSmaＩ部位にクローニングし、蛍光ＤＮＡシーケンサー（Applied Biosystems）を用いて塩基配列を決定した。得られた塩基配列を配列番号１に示す。この塩基配列から推定されるアミノ酸配列（配列番号２）は、マウスのステアロイル-CoA不飽和化酵素と有意な相同性を示した〔第１図：des 9 var 断片がコードするアミノ酸配列とマウスのステアロイル－ＣｏＡ不飽和化酵素（ＭＳＣＤ２）のアミノ酸配列の比較を示す〕。

次に、des 9 var 断片をプローブとして、Anacystis nidulansのゲノムＤＮＡをサザン分析した。制限酵素XhoＩ，PstＩおよびBamHＩの各々を単独で用いて約0.1μg のAnacystis nidulansのゲノムＤＮＡを切断し、0.8％アガロースゲル電気泳動でＤＮＡ断片を分離後、ナイロンメンブレン（Hybond-N$^+$; Amersham）にブロッティングした。プローブＤＮＡはMultiprime DNA labelling Kit(Amersham）を用いて〔α－^{32}P〕ｄＣＴＰで標識した。６×SSPE[１×SSPEは10mMリン酸緩衝液（pH7.0），１mM EDTA,0.15M NaCl],0.2％ＳＤＳおよび100μg/mlニシン精子ＤＮＡから成る液中で55℃、16時間インキュベーションしてプローブＤＮＡとメンブレンを反応させた。その後、メンブレンを２×SSC〔１×SSCは0.15M NaCl,15mMクエン酸ナトリウム〕中で室温、15分を２回、次いで0.1×SSC中で40℃、15分を２回振とうして洗い、オートラジオグラフィーを行なった。その結果、いずれの制限酵素で切断した場合も１本のＤＮＡ断片のみが検出された（第２図：図中、Ｎｏｎはゲノム DＮＡを制限酵素で切断していないことを示す）。

〔実施例２〕des 9 var 断片と相同性の高いAnacystis nidulansゲノム中のＤＮ

Ａ鎖のクローニング

Anacystis nidulans R2-SPc （東京大学分子細胞生物学研究所より分譲）の培養およびゲノムＤＮＡの調製は、Anabaena variabilis の場合と同様に行なった。約100μgのゲノムＤＮＡをSau3AIで部分消化した後、Molecular Cloning 2nd edition, pp. 2. 85-2. 87(Sambrook, J. et al. eds., Cold Spring Harbor Laboratory, 1989）の方法に従って、ショ糖密度勾配下での超遠心分離により約９から23kbpのＤＮＡ断片を回収した。これをBamHＩとHindIIIで切断したラムダファージベクターλDASH II(Stratagene）にクローニングした後、ファージ粒子にパッケージングしAnacystis nidulansのゲノムＤＮＡライブラリーを得た。このファージライブラリーを大腸菌P2392 に感染させ、ＮＺＹＭ培地を入れた直径約15cmのシャーレにまいて総数約10万個のプラークを形成させた後、ナイロンメンブレン （Hybond-N$^+$; Amersham）にブロッティングした。上記のサザン分析と同様に、〔$\alpha-{}^{32}$Ｐ〕ｄＣＴＰで標識したdes 9 var 断片をこのメンブレンと反応させ、オートラジオグラフィーによって検出した陽性ファージを再度同様にスクリーニングすることにより、シグナル強度の異なる約30個のファージクローンを得た。この中から任意に12クローンを選び、常法に従ってファージＤＮＡを得た。得られたファージＤＮＡを数種類の制限酵素で切断し、0.8％アガロースゲル電気泳動で分離後、ナイロンメンブレンにブロッティングした。このメンブレンを上記のスクリーニングと同じ条件でサザン分析し、プローブＤＮＡとハイブリダイズするＤＮＡ断片の長さとそのシグナル強度を比較した。その結果、λ５とλ15の２クローンが最も強いシグナルを示し、またインサートＤＮＡ断片の長さもそれぞれ11および15kbpであったため目的のＯＲＦ全体を含むのに十分と判断し、この２クローンのインサートＤＮＡにつき更に幾つかの制限酵素で切断してサザン分析を行なった。その結果XhoIで切断しハイブリダイズすると、２クローンとも約５kbpのＤＮＡ断片が検出されたので、これをpBluescript SK-(Stratagene）のXhoＩサイトにサブクローニングし、λ５とλ15由来のＤＮＡ断片をそれぞれ含むプラスミドｐ５Ｘとｐ15Ｘを得た。ｐ５Ｘとｐ15Ｘの詳細な制限酵素地図を作り比較したところ、ともに同一のゲノムＤＮＡ断片を含むと判断された〔第３図：λ５、λ15およびｐ15ＸのインサートＤＮＡ断片の相互関係

を示す。網かけした長方形はスクリーニングの過程でプローブのdes 9 var 断片がハイブリダイズしたＤＮＡ断片を示す。太い矢印はdes 9 nid（後述）の領域とセンス鎖の方向を示す。細い矢印はdes 9 nid を含む領域のシーケンスの方向を示す。5, 1. 25および0. 5kbpの各バーは左の各図におけるサイズマーカーを示す。制限酵素の略号は、B, BamHI ; H, HindIII ; N, NotI ; Hp, HpaI ; RI, EcoRI ; RV, EcoRV ; S, SalI ; P, PstI ; X, XhoIを示す〕。

そこで、制限酵素あるいはExoIIIによるディリーションプラスミドをｐ15Ｘより作成し、des 9 var 断片がハイブリダイズする領域を含む約２kbpのＤＮＡ断片の塩基配列を蛍光ＤＮＡシーケンサーを用いて決定した（第３図）。その結果そのＤＮＡ断片中には834bpからなるＯＲＦ（des 9 nid）が存在し（配列番号３）、278残基のアミノ酸がコードされていると推定された（配列番号４）。先にクローニングしたAnabaena variabilis 由来のdes 9 var 断片がコードしているアミノ酸配列（配列番号２）との相同性は約80％であった。さらに、核酸およびアミノ酸配列の解析ソフト（ＧＥＮＥＴＹＸ；ソフトウエア開発）と核酸およびアミノ酸配列のデータベース（ＥＭＢＬおよびＤＤＢＪ）を用いて相同性の高いアミノ酸配列の検索を行なったところ、マウスのステアロイル－ＣｏＡ不飽和化酵素との相同性が全体では約３０％であるが局所的に非常に高いこと〔第４図：des 9 nidとマウスのステアロイル－ＣｏＡ不飽和化酵素（ＭＳＣＤ２）のアミノ酸配列の比較〕から、取得したdes 9 nidは脂肪酸を不飽和化する酵素をコードすることが強く示唆された。

〔実施例３〕　des９nid遺伝子の大腸菌での発現による活性測定

Anacystis nidulansは不飽和化酵素として脂質に結合した飽和脂肪酸の９位を不飽和化するΔ９位不飽和化酵素活性しか持たない（Bishop, D. G. et al., Plant Cell Physiol., 27:1593, 1986）ため、des９nidがコードするポリペプチドを大腸菌で発現させ活性測定することを試みた。

p15Xから直接発現させることは困難なので、大腸菌での発現用のベクターを作成した。即ち、ベクターとしてpET3a(Novagen)用い、そのNdeIとBamHIの間にdes９nidをアミノ末端に余計なアミノ酸を付けない用にしてクローニングすることを以下のようにして行なった。des９nidのコードするタンパクのＣ末端側直後にBamHIサイトを入れるために、Ｃ末端を鋏む２箇所の塩基配列を使ってＰＣＲ反応を行なった。即ち、

センスプライマー；5'-ACGTCATGGCCTGCAGT（下線はPstIサイト）（配列番号９）

アンチセンスプライマー；5'-CGCGGATCCTTAGTTGTTTGGAGACG（１重線はBamHIサイト、２重線はストップコドン）（配列番号１０）

p15Xを鋳型として上記の２つのプライマーを用いてＰＣＲ反応を行なうと約１４０ｂｐの産物が得られ、これをpUC19のSmaI部位にサブクローニングして塩基配列に間違いのないことを確認した。この結果得られたプラスミドのBamHIの下流にはEcoRI部位が生じた。これをEcoRIとPstIで順に切断し、一方、p15Xも同じ制限酵素で切断することにより、ストップコドンの直後にBamHI部位を導入した。このプラスミドをSalIで切断した後、４種のdNTP存在下でDNAポリメラーゼKlenow断片を用いてFill in反応を行ない、引き続きHindIIIで切断した。これに、以下の２種の合成DNAから成るアダプターを導入する事によりアミノ末端側にNdeI部位を導入した。即ち、

5'-CATATGACCCTTGCTATCCGACCCA（下線はNdeI）（配列番号１１）及び

5'-AGCTTGGGTCGGATAGCAAGGGTCATATG（１重線はNdeIサイト、２重線はHindIIIの一部）（配列番号１２）

を等モル量混合しアダプターとした。以上のようにして出来たプラスミド（pDes9Nde）を、常法（Molecular cloning pp. 250-251; 1982）に従って調整した大腸菌株BL21(DE3)（Novagen)のコンピテントセルに導入し、アンピシリン耐性

による選別により形質転換株ＢＬＤＥＳ１を得た。

ＢＬＤＥＳ１及びpET3aのみを有するBL21株（ＢＬ１）を100mlのM9培地（200 μg/mlのアンピシリン，4 mg/ml グルコース、10μM FeCl3, 0.5μg/mlビタミンB1, 1 mg/mlカザミノ酸を含む）に接種し、３７℃で培養した。培養液の濁度が、波長600nmで0.5O.D.になるまで培養を続けた後、イソプロピルチオガラクトシド(IPTG)を最終濃度１mMになるように加えた。更に１時間培養し、Δ９位不飽和化酵素遺伝子の発現を誘導した。回収した大腸菌ペレットを1.2% NaClで洗った後、脂質を抽出した。脂質はBlighとDyerの方法（Can J. Biochem. Physiol., 37: 911, 1959）に従って抽出し、2.5 mlの５％塩酸メタノールで完全密封化して85℃２時間半反応させ脂肪酸をメチル化した。生じた脂肪酸メチルエステルを2.5 mlのヘキサンで４回抽出し、窒素ガスで溶媒を除去して濃縮した。脂肪酸メチルエステルの分析には、ガスクロマトグラフィーを用いた。脂肪酸の同定は標準脂肪酸メチルとの保持時間を比較して行なった。定量にはクロマトパックC-R7A plus（島津製作所）を用いた。結果を次の第１表に示す。

第１表.　大腸菌の脂肪酸組成

菌株名	１６：０	１６：１	１８：１（１１）	その他
ＢＬ１（０時間）	４７	２０	２９	４
ＢＬ１（１時間）	５０	１７	２９	４
ＢＬＤＥＳ１（０時間）	４４	２２	３０	４
ＢＬＤＥＳ１（１時間）	４０	２８	２８	４

ここで時間はIPTGによるタンパクの誘導時間を示す。

ＢＬＤＥＳ１では１６：１が増加していることが明らかである。即ち、本遺伝子は１６：０への不飽和化活性を有することが示された。

また、これらの菌株を0.1 mMのステアリン酸を含むM9培地で培養し、同様に比較したところ、ＢＬ１株に比べＢＬＤＥＳ１では１６：１のみならず、１８：１（９）も生成し、des 9 nid がコードするポリペプチドは１６：０ばかりでなく１８：０も基質として不飽和脂肪酸を作出することが示された。

〔実施例４〕 des９nid遺伝子のタバコ植物体への導入

Anacystis nidulans由来のdes９nid遺伝子を次のようにしてタバコに組み込んだ。

（１）植物発現用ベクタープラスミドの構築

pDes9NdeをSacIとSalIで切断する事により両酵素の切断部位で挟まれたdes９nid遺伝子断片が得られる。一方、エンドウのRuBisCO遺伝子を含むクローンpSNIP9（Schreicherら、EMBO J. 4,25(1985)）から葉緑体へのtransit配列をHindIIIとSphIで切り出し、それと同一の制限酵素で切断したpUC118にクローニングすることにより、transit配列の下流にマルチクローニングサイトを有するプラスミド（pTRA3）を得た。このHindIIIサイトを切断後Klenow酵素でFill inしXbaIリンカーをいれた（pTRA3X）。このプラスミドpTRA3XをSal IとSac Iで切断し、さきに同一の制限酵素で切断する事によって得たdes９nid遺伝子断片を挿入した（pTRA3Xdes9）。このプラスミドではRuBisCOのtransit配列に引き続き、それと同一の読み枠でdes９nid遺伝子が翻訳される。これをSac IとXba Iで切断して次に述べる植物用のベクターに挿入する。植物発現型バイナリープラスミドpBI121(Clonetech)を制限酵素SacIとXbaIで切断して得たプラスミドpBI(-GUS)はβ-Glucuronidase遺伝子（GUS遺伝子）を含んでおらず、これにカリフラワーモザイクウイルスの35Sプロモーターとノパリン合成酵素（NOS）ターミネーターの間に前述した導入遺伝子を挿入することにより、植物への導入用ベクター（pBI121(-GUS)Rbsc-des9）を得た。

（２）pBI121(-GUS)Rbsc-des9のアグロバクテリウムへの導入

Agrobacterium tumefaciens LBA4404（Clonetech)を50mlのYEB培地（１l当たりビーフエキス５g、酵母エキス１g、ペプトン１g、ショ糖５g、2mM MgSO4(pH7.4)）に接種し、28℃で24時間培養後、培養液を3,000rpm、４℃、20分の遠心で集菌した。菌体を10mlの１ mM Hepes-KOH(pH7.4)で３回洗った後、３mlの10%グリセロールで１回洗い、最終的に３mlの10%グリセロールに懸濁してＤＮＡ導入用アグロバクテリウムとした。

このようにして得た菌液50μl及び前記のプラスミドpBI121(-GUS)Rbsc-des9 １μgをキュベットに入れ、エレクトロポレーション装置（Gene Pulser;

BioRad）を用いて 25μF、 2500V、 200Ωの条件で電気パルスをかけ、プラスミドＤＮＡをアグロバクテリウムに導入した。この菌液をエッペンドルフチューブに移し、800μlの SOC培地（１ l当たりトリプトン 20 g、酵母エキス５ g、 NaCl 0.5 g、2.5 mM KCl、10 mM MgSO4，10 mM MgCl2，20 mM グルコース、pH7.0）を加え、28℃で 1.5時間静置培養した。この培養液 50μlを、 100 ppmのカナマイシンを含む YEB寒天培地（寒天 1.2%）上にまき、 28℃で２日間培養した。

得られたコロニー群からシングルコロニーを選び、このコロニーからアルカリ法でプラスミドＤＮＡを調整した。このプラスミドＤＮＡを適当な制限酵素で消化後、１％アガロースゲル電気泳動によりＤＮＡ断片を分離し、32Ｐでラベルしたdes９nid遺伝子断片をプローブとしたサザン分析により、プラスミドpBI121(-GUS)Rbsc-des9を含んでいることを確認した。このAgrobacterium tumefaciensをALBBSDESと呼ぶ。

（３）タバコの形質転換

上記の菌株ALBBSDESを、50ppmのカナマイシンを含むLB液体培地で28℃、２時間振とう培養した。培養液1.5 mlを 10,000rpm、３分間遠心して集菌後、カナマイシンを除くために１mlのLB培地で洗浄した。更に10,000rpm、３分間遠心して集菌後、1.5 mlのLB培地に再懸濁し感染用菌液とした。

タバコへの感染に当たっては、若い葉を採取し、0.5%次亜塩素酸ナトリウム水溶液に10分間浸せき後、滅菌水で３回洗い、滅菌済みの濾紙上で水を拭って感染用の葉とした。この葉を１片が１cm² になるようにメスで無菌的に切断し、上記のアグロバクテリウムの菌液上に葉の裏を上にして置き、２分間静かに振とうした後、滅菌済みの濾紙上に葉を置いて過剰のアグロバクテリウムを除いた。シャーレ内のMS-B5培地（ベンジルアデニン1.0 ppm、ナフタレン酢酸 0.1 ppm、及び寒天 0.8 %を含む）（ Murashige, T. and Skoog, F. Plant Physiol., 15: 473, (1962)）上に、ワットマン No. 1濾紙（φ 7.0 cm）を置き、この濾紙に裏を上にして葉を置いた。シャーレをパラフィルムでシールし、 16時間明、８時間暗の周期で 25℃、２日間培養した。ついでクラフォラン 250 ppmを含むMS-B5培地上に移し、同様に 10日間培養してアグロバクテリウムを除去した。

更にクラフォラン 250 ppm及びカナマイシン 100 ppmを含む MS-B5培地上に置床し、同様に７日間培養した。この間に葉片の周囲がカルス化し、シュート原基が生じた。更に 10日間培養後、伸張したシュートをクラフォラン 250 ppm及びカナマイシン 100 ppmを含む MS-HF培地（ベンジルアデニン及びナフタレン酢酸を含まない MS-B5培地）に置床した。 10日間培養後、発根したシュートをカナマイシン耐性の形質転換体とし、プラントボックス内のクラフォラン 250 ppmを含む MS-HF培地に移植した。

〔実施例５〕形質転換タバコのゲノムサザン及びノーザン分析

目的遺伝子の導入を確認するため、カナマイシン耐性のタバコからＤＮＡを抽出し、サザン及びノーザン分析を行った。ゲノムＤＮＡの抽出法はＣＴＡＢ法で成書（Rogers, S. O. & Bendich, A. J.; Plant Molecular Biology Manual A6; 1(1988)）に従って行なった。即ち、２ｇのタバコの葉を液体窒素内で粉砕し、ＣＴＡＢ抽出緩衝液でゲノムＤＮＡを得た。１０μｇのＤＮＡを制限酵素EcoRIとXbaIで切断後0.7%アガロースゲルで電気泳動し、その後ナイロン膜（Hybond N+; Amersham）に0.4 N NaOHで転写した。この膜にpTRA3Xdes9からtransit付きの不飽和化酵素遺伝子をプローブとして、、６５℃で１６時間ハイブリダイゼーションすることにより目的遺伝子がタバコゲノムに組み込まれていることを確認した。

また、導入遺伝子の発現を調べるために、タバコの葉約２ｇからＲＮＡの分析を行なった。方法はグアニジウムチオシアン酸による抽出を行ない（Nagy, F. ら: Plant Molecular Biology Manual B4; 1 (1988)）、poly(A)+RNAをホルムアルデヒド入りのアガロースゲルで電気泳動後、ナイロン膜（Hybond N; Amersham）に転写し、サザン法と同様のハイブリダイゼーションにより分析した。様々の量のＲＮＡを発現している個体があったが、その中から発現量の多い個体について脂質分析を行なった。

〔実施例６〕形質転換タバコの脂質の脂肪酸分析

実施例５でＲＮＡの高発現が確認されたタバコ形質転換体、及び対照としてpBI121で形質転換したタバコの葉から、以下の方法によりホスファチジルグリセロール（ＰＧ）、スルフォキノボシルジアシルグリセロール（ＳＱＤＧ）等の脂

質を調整し、その脂肪酸組成を分析した。なお、一部の個体からは根の脂質も分析した。

（１）全脂質の抽出

脂質の抽出はBligh-Dyer法（Can J. Biochem. Physiol., 37: 911, 1959）で行なった。湿重量２ｇの葉（一部の根を試料とするときは１ｇ）をメスで細断し、これに20 mlのクロロホルム：メタノール（１：２、体積比）を加え、ホモジナイザーで葉を破砕後、 15分間静置した。これにクロロホルム 12ml及び蒸留水12ml を加え激しく混合した後、3000rpm 、４℃、30分間の遠心で水層と有機層の２層に分け、有機層（下層）を回収した。これに適当量のエタノールを加えて、ロータリーエバポレーターを用い、30℃減圧下で溶媒を除いた。これを２ mlのクロロホルム：メタノール（１：４、体積比）に溶かし、全脂質抽出物とした。この一部を５％メタノール性塩酸を用いて後述の方法により処理することで、メチル化脂肪酸を得た。

（２）脂質の分画

DEAE-Toyopearl 650C（東ソー）の懸濁液2.5mlを１ M酢酸ナトリウム水溶液(pH7.0)25 mlと混ぜ酢酸型とした。これを、蒸留水、メタノールで順次洗浄し、最後にメタノールに懸濁して、内径２ cmのカラムに高さ1.5cmまで詰め、更に50 mlのクロロホルム：メタノール（１：４、体積比）で洗浄した。

次に、全脂質抽出物をカラムにかけ、50 mlのクロロホルム：メタノール（１：４、体積比）でモノガラクトシルジアシルグリセロール（ＭＧＤＧ）、ジガラクトシルジアシルグリセロール（ＤＧＤＧ）、ホスファチジルエタノールアミン（ＰＥ）、ホスファチジルコリン（ＰＣ）を溶出して、中性脂質（ＭＧＤＧ、ＤＧＤＧ、ＰＥ、ＰＣ）画分とした。次に５mlの酢酸でホスファチジルセリン（ＰＳ）を溶出して除き、20mlのクロロホルム：メタノール（１：４、体積比）で酢酸を洗浄した後、50 mlのクロロホルム：メタノール：10 M酢酸アンモニウム水溶液（20:80:0.2、体積比）でＰＧ、ＳＱＤＧ、ホスファチジルイノシトール（ＰＩ）を含む画分を得た。この画分に 15mlのエタノールを加え、減圧下で溶媒を除いた。これを0.2mlのクロロホルム：メタノール（２：１、体積比）に溶かし、酸性脂質（ＰＧ、ＳＱＤＧ、ＰＩ）画分とした。

ＭＧＤＧ、ＤＧＤＧ、ＰＥ、ＰＣ画分は、ケイ酸カラムクロマトグラフィー（イアトロビーズ、ヤトロン社）により、さらに分画した。即ち、クロロホルム１mlに溶かした試料をクロロホルムで平衡化したカラムにかけ、クロロホルム：アセトン（４：１）、アセトン、メタノールで順に溶出すると、糖脂質（ＭＧＤＧ、ＤＧＤＧ）はアセトンで、リン脂質（ＰＣ、ＰＥ）はメタノールで溶出された。

（３）薄層クロマトグラフィー（TLC）によるＰＧの単離精製と脂肪酸分析

（２）で得た画分をシリカゲルーTLCプレート#5721（Merck）で分離した。展開溶媒としては、酸性脂質の場合はクロロホルム：アセトン：メタノール：酢酸：水（50:20:10:15:5、体積比）を、中性脂質の場合はクロロホルム：メタノール：水(70:21:3、体積比)を用いた。TLCで分離後、プリムリン（８０％アセトン溶液）を噴霧して紫外線光下で蛍光発色させ、標準となる脂質と移動度を比較することにより各クラスの脂質の画分を推定し、発色した脂質をシリカゲルごと削り取りネジ栓付試験管に入れた。この脂肪酸組成を推定する場合には、この試験管に３ mlのメタノール性５％塩酸を加え、完全密封下85℃で２時間半反応させ、脂肪酸メチル化した。一方、ｓｎ－１、２ごとの脂肪酸組成を決めるために、削り取ったシリカゲルから５ｍｌのクロロホルム：メタノール（２：１）混液で脂質を回収し、乾固した後、１ mlの50 mM TrisCl (pH 7.2)及び0.05 % Triton X-100 を加え、激しく攪拌して脂質を分散させて、クモノスカビ（Rhizopus delemar）由来のリパーゼ（２５００Ｕ；ベーリンガー社）を加え３７℃で３０分間保温することにより選択的にｓｎ－１位の脂肪酸を分解させた。この反応産物を濃縮後、ＴＬＣ（クロロホルム：アセトン：メタノール：酢酸：水＝１０：４：２：３：１）により未反応の脂質、リゾ体、及び脂肪酸に分離した。これらもゲルから回収し前述のようにメタノール性塩酸でメチル化脂肪酸を得た。生じた脂肪酸メチルエステルを３ mlのヘキサンで４回抽出し、減圧下で溶媒を除去して濃縮した。脂肪酸メチルの分析には、ガスクロマトグラフィーを用いた。脂肪酸の同定は標準脂肪酸メチルとの保持時間を比較して行なった。定量にはクロマトパックC-R7A plus（島津製作所）を用いた。全脂質の結果を第２表、PGについて第３表、その他の代表的な脂質ごとの分析結果を第４表に示す。表は、対

照植物体については2個体、形質転換体については独立した2又は3個体の分析値の平均値を示している。

ＰＧに結合した脂肪酸分析の結果から、Anacystis nidulans由来の脂肪酸不飽和化酵素を発現している形質転換タバコでは１６：０（パルミチン酸）が大幅に減り、そのかわりに１６：１ｃｉｓが増えている事、また、少量在った１８：０もほとんど無くなり、逆に１８：１が増えているいることが判明した。その結果、飽和脂肪酸（１６：０＋１６：１ｔｒａｎｓ＋１８：０（ステアリン酸））含量は、対照のタバコでは７０％であるのに対し、不飽和化酵素の遺伝子を形質転換したタバコでは５５％と著しく低くなっている。ＰＧのｓｎ－１、２位別の分析結果から、ｓｎ－２は９８％以上飽和脂肪酸（１６：０又は１６：１ｔｒａｎｓ）で占められており、新たに遺伝子導入により生成した１６：１はすべてｓｎ－１にあることが判明した。従って、この不飽和化酵素遺伝子を形質転換したタバコのＰＧのｓｎ－１位の飽和脂肪酸は極めて少なくなっていることが明らかである。従って、ｓｎ－１、２両位共に、飽和脂肪酸から成る、所謂、飽和分子種の量も大幅に減少し、脂質の分子種の組成上著しく低温に耐性な型に変化した事がわかる。

一方、その他の脂質のＭＧＤＧ、ＤＧＤＧ、ＳＱＤＧ、ＰＣ、ＰＥ、ＰＩでも、１６：０の減少と、それに呼応した１６：１の１０％前後の増加が明らかであり、また、１８：０の不飽和化も進んでいた。このうち、ＭＧＤＧとＤＧＤＧについては１６：１の生成は主としてｓｎ－１位にあったが、ｓｎ－２位からも少量検出された。ＭＧＤＧ、ＤＧＤＧ、ＳＱＤＧ及びＰＧは主に葉緑体に存在する脂質であり、ラン藻であるAnacystis nidulansの不飽和化酵素を高等植物の葉緑体で発現させることにより驚くほど不飽和化が進展したことがわかる。それにも増して、これらの４種の脂質はAnacystis nidulansの膜にも存在する物であり、不飽和化の基質になる可能性は高かったが、それ以外のＰＣ、ＰＥ及びＰＩはAnacystis nidulansの膜には存在しない脂質であり、しかも高等植物では主に葉緑体外に存在する脂質であることから、それらにおいてもパルミチン酸、及びステアリン酸が不飽和化されたのは驚くべきことである。

このように、形質転換タバコの脂質分析の結果から、Anacystis nidulans由来の脂肪酸不飽和化酵素が、高等植物であるタバコの形質転換体において、ほとんど総ての脂質の１６：０と１８：０を極めて効率良く不飽和化できることを本実施例は証明した。

また、根の全脂質について、脂肪酸分析をした結果を第５表に示す。

第５表．根の全脂質の脂肪酸分析

植物	16:0	16:1	16:2	16:3	18:0	18:1	18:2	18:3	Σ16:0+18:0
非形質転換体	26	0	0	0	5	2	47	21	31
形質転換体	17	13	0	0	2	4	58	6	19

この結果から、Anacystis nidulans由来の脂肪酸不飽和化酵素は、驚くべきことに、葉のみならず根においても１６：０と１８：０の不飽和化を触媒したこと

がわかる。このことは、本発明の脂肪酸不飽和化酵素遺伝子が植物の低温耐性を変化させる可能性ばかりでなく、不飽和脂肪酸含量を増やす可能性を有し、植物を油の原料とする産業においても有用であることを示す。

〔実施例７〕形質転換タバコの低温耐性試験

上記のＲＮＡの発現解析及び脂質分析で有望と思われた個体については、自殖することにより次世代の種子を採取した。その一部をカナマイシン 800 ppmを含む MS-HF培地に蒔き、２５℃、１６時間明、８時間暗の日長で２週間栽培後にカナマイシン耐性の実生を選抜した。この実生をプラントボックスに移植して、更に４週間栽培した。また、コントロールとして、pBI121により形質転換した個体についても、上記の操作を行った。

次に、４℃連続光のもとで１１日間低温処理した後、２５℃で２日間栽培した。その結果、コントロール植物（pBI121により形質転換した植物）では葉に対して大幅な萎縮症状及びクロロシスが観察されたのに対し、形質転換植物ではほとんど傷害は観察されなかった。従って、不飽和化酵素遺伝子の導入により低温耐性が向上したと推定された。

産業上の利用可能性

本発明のΔ９位不飽和化酵素をコードする遺伝子を植物に導入することにより、植物に低温耐性を付与することおよび植物中の不飽和脂肪酸含量を増やすことが可能となった。

請 求 の 範 囲

1. 脂質に結合した脂肪酸のΔ9位を不飽和化する活性を有するタンパク質をコードする遺伝子。

2. 脂質に結合した脂肪酸のΔ9位を不飽和化する活性を有するタンパク質が実質的に配列番号4に記載されたアミノ酸配列を有するものである請求の範囲第1項記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチド。

3. 脂質に結合した脂肪酸のΔ9位を不飽和化する活性を有するタンパク質をコードする遺伝子が配列番号3に記載の塩基配列を含むＤＮＡ鎖である請求の範囲第1項記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチド。

4. 請求の範囲第1項乃至第3項のいずれかの項記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドを含むベクター。

5. 請求の範囲第1項乃至第3項のいずれかの項記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドが導入された植物細胞。

6. 請求の範囲第5項記載の植物細胞を分化させて植物体を再生させることを特徴とする植物の作出方法。

7. 請求の範囲第1項乃至第3項のいずれかの項記載の遺伝子又は当該遺伝子の一部を含むポリヌクレオチドが導入された植物。

(54) Title: PLANT DESATURASES - COMPOSITIONS AND USES

(57) Abstract

By this invention, compositions and methods of use of plant desaturase enzymes, especially Δ-9 desaturases, are provided. Of special interest are methods and compositions of amino acids and nucleic acid sequences related to biologically active plant desaturases as well as sequences, especially nucleic acid sequences, which are to be used as probes, vectors for transformation or cloning intermediates. Biologically active sequences may be found in a sense or anti-sense orientation as to transcriptional regulatory regions found in various constructs.

PLANT DESATURASES - COMPOSITIONS AND USES

This application is a continuation-in-part of USSN 07/494,106 filed on March 16, 1990 and a continuation-in-part of USSN 07/567,373 filed on August 13, 1990 and a continuation-in-part of USSN 07/615,784 filed on November 14, 1990.

Technical Field

The present invention is directed to desaturase enzymes relevant to fatty acid synthesis in plants, enzymes, amino acid and nucleic acid sequences and methods related thereto, and novel plant entities and/or oils and methods related thereto.

INTRODUCTION

Background

Novel vegetable oils compositions and/or improved means to obtain or manipulate fatty acid compositions, from biosynthetic or natural plant sources, are needed. Depending upon the intended oil use, various different oil compositions are desired. For example, edible oil sources containing the minimum possible amounts of saturated fatty acids are desired for dietary reasons and alternatives to current sources of highly saturated oil products, such as tropical oils, are also needed.

One means postulated to obtain such oils and/or modified fatty acid compositions is through the genetic engineering of plants. However, in order to genetically engineer plants one must have in place the means to transfer genetic material to the plant in a stable and heritable manner. Additionally, one must have nucleic acid sequences capable of producing the desired phenotypic result, regulatory regions capable of directing the correct application of such sequences, and the like. Moreover, it

should be appreciated that to produce a desired modified oils phenotype requires that the Fatty Acid Synthetase (FAS) pathway of the plant is modified to the extent that the ratios of reactants are modulated or changed.

Higher plants appear to synthesize fatty acids via a common metabolic pathway in plant plastid organelles (i.e., chloroplasts, proplastids, or other related organelles) as part of the FAS complex. Outside of plastid organelles, fátty acids are incorporated into triglycerides and used in plant membranes and in neutral lipids. In developing seeds, where oils are produced and stored as sources of energy for future use, FAS occurs in proplastids.

The production of fatty acids begins in the plastid with the reaction between Acyl Carrier Protein (ACP) and acetyl-CoA to produce acetyl-ACP. Through a sequence of cylical reactions, the acetyl-ACP is elongated to 16- and 18- carbon fatty acids. The longest chain fatty acids produced by the FAS are 18 carbons long. Monunsaturated fatty acids are also produced in the plastid through the action of a desaturase enzyme.

Common plant fatty acids, such as oleic, linoleic and α-linolenic acids, are the result of sequential desaturation of stearate. The first desaturation step is the desaturation of stearoyl-ACP (C18:0) to form oleoyl-ACP (C18:1) in a reaction often catalyzed by a Δ-9 desaturase, also often referred to as a "stearoyl-ACP desaturase" because of its high activity toward stearate the 18 carbon acyl-ACP. The desaturase enzyme functions to add a double bond at the ninth carbon in accordance with the following reaction (I):

$$\text{Stearoyl-ACP} + \text{ferredoxin(II)} + O_2 + 2H^+ \rightarrow \text{oleoyl-ACP} + \text{ferredoxin (III)} + 2H_2O.$$

Δ-9 desaturases have been studied in partially purified preparations from numerous plant species. Reports indicate that the protein is a dimer, perhaps a homodimer, displaying a molecular weight of 68 kD (±8 kD) by gel-filtration and a molecular weight of 36 kD by SDS-polyacrylamide gel electrophoresis.

In subsequent sequential steps for triglyceride production, polyunsaturated fatty acids may be produced. These desaturations occur outside of the plastid as a result of the action of membrane-bound enzymes. Additional double bonds are added at the twelve position carbon and thereafter, if added, at the 15 position carbon through the action of Δ-12 desaturase and Δ-15 desaturase, respectively.

Obtaining nucleic acid sequences capable of producing a phenotypic result in FAS, desaturation and/or incorporation of fatty acids into a glycerol backbone to produce an oil is subject to various obstacles including but not limited to the identification of metabolic factors of interest, choice and characterization of a protein source with useful kinetic properties, purification of the protein of interest to a level which will allow for its amino acid sequencing, utilizing amino acid sequence data to obtain a nucleic acid sequence capable of use as a probe to retrieve the desired DNA sequence, and the preparation of constructs, transformation and analysis of the resulting plants.

Thus, the identification of enzyme targets and useful plant sources for nucleic acid sequences of such enzyme targets capable of modifying fatty acid compositions are needed. Ideally, an enzyme target will be amenable to one or more applications alone or in combination with other nucleic acid sequences relating to increased/decreased oil production, the ratio of saturated to unsaturated fatty acids in the fatty acid pool, and/or to novel oils compositions as a result of the modifications to the fatty acid pool. Once enzyme target(s) are identified and qualified, quantities of protein and purification protocols are needed for sequencing. Ultimately, useful nucleic acid constructs having the necessary elements to provide a phenotypic modification and plants containing such constructs are needed.

Relevant Literature

A 200-fold purification of *Carthamus tinctorius* ("safflower") stearoyl-ACP desaturase was reported by McKeon & Stumpf in 1982, following the first publication of their protocol in 1981. McKeon, T. & Stumpf, P. *J.Biol.Chem.* (1982) *257*:12141-12147; McKeon, T. & Stumpf, P. *Methods in Enzymol.* (1981) *71*:275-281.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 provides amino acid sequence of fragments relating to *C. tinctorius* desaturase. Fragments F1 through F11 are also provided in the sequence listing as SEQ ID NO: 1 through SEQ ID NO: 11, respectively. Each fragment represents a synthesis of sequence information from peptides originating from different digests which have been matched and aligned. In positions where there are two amino acids indicated, the top one corresponds to that found in the translation of the cDNA; the lower one was detected either as a second signal at the same position of one of the sequenced peptides, or as a single unambiguous signal found in one or more of the overlapping peptides comprising the fragment. Residues in F9 shown in lower case letters represent positions where the called sequence does not agree with that predicted from the cDNA, but where the amino acid assignment is tentative because of the presence of a contaminating peptide. The standard one letter code for amino acid residues has been used. X represents a position where no signal was detectable, and which could be a modified residue. F1 corresponds to the N-terminal sequence of the mature protein. The underlined region in F2 is the sequence used in designing PCR primers for probe synthesis.

Fig. 2 provides a cDNA sequence (SEQ ID NO: 12) and the corresponding translational peptide sequence (SEQ ID NO: 13) derived from *C. tinctorius* desaturase. The cDNA sequence includes both the plastid transit peptide encoding sequence and the sequence encoding the mature protein.

Fig. 3 provides cDNA sequence of *Ricinus communis* desaturase. Fig. 3A provides preliminary partial cDNA sequence of a 1.7 kb clone of *R. communis* desaturase (SEQ ID NO: 14). The sequence is from the 5' end of the clone. Fig. 3B provides the complete cDNA sequence of the approximately 1.7 kb clone (SEQ ID NO: 15) and the corresponding translational peptide sequence (SEQ ID NO: 16).

Fig. 4 provides sequence of *Brassica campestris* desaturase. Fig. 4A represents partial DNA sequence of a 1.6 kb clone pCGN3235 (SEQ ID NO: 17), from the 5' end of the clone. Fig. 4B represents partial DNA sequence of a 1.2 kb clone, pCGN3236, from the 5' end of the clone (SEQ ID NO: 18). Initial sequence for the 3' ends of the two *B. campestris* desaturase clones indicates that pCGN3236 is a shorter cDNA for the same clone as pCGN3235. Fig. 4C provides complete cDNA sequence of *B. campestris* desaturase above, pCGN3235 (SEQ ID NO: 19) and the corresponding translational peptide sequence (SEQ ID NO: 20).

Fig. 5 provides preliminary partial cDNA sequence of *Simmondsia chinensis* desaturase (SEQ ID NO: 43). The translated amino acid sequence is also shown.

Fig. 6 shows the design of forward and reverse primers (SEQ ID NO: 21 through SEQ ID NO: 26) used in polymerase chain reaction (PCR) from the sequence of *C. tinctorius* desaturase peptide "Fragment F2" (SEQ ID NO: 2).

Fig. 7 provides maps of desaturase cDNA clones showing selected restriction enzyme sites. Fig. 7A represents a *C. tinctorius* clone, Fig. 7B represents a *R. communis* clone, and Fig. 7C represents a *B. campestris* clone.

Fig. 8 provides approximately 3.4 kb of genomic sequence of Bce4 (SEQ ID NO: 27).

Fig. 9 provides approximately 4 kb of genomic sequence of Bcg 4-4 ACP sequence (SEQ ID NO: 28).

Fig. 10 provides a restriction map of cloned λCGN 1-2 showing the entire napin coding region sequence as well as extensive 5' upstream and 3' downstream sequences (SEQ ID NO: 29).

SUMMARY OF THE INVENTION

By this invention, compositions and methods of use of plant desaturase enzymes, especially Δ-9 desaturases, are provided. Of special interest are methods and compositions of amino acids and nucleic acid sequences related to biologically active plant desaturases as well as sequences, especially nucleic acid sequences, which are to be used as probes, vectors for transformation or cloning intermediates. Biologically active sequences may be found in a sense or anti-sense orientation as to transcriptional regulatory regions found in various constructs.

A first aspect of this invention relates to C. tinctorius Δ-9 desaturase substantially free of seed storage protein. Amino acid sequence of this desaturase is provided in Fig. 2 and as SEQ ID NO: 13.

DNA sequence of *C. tinctorius* desaturase gene (SEQ ID NO: 12) is provided, as well as DNA sequences of desaturase genes from a *Ricinus* (SEQ ID NO: 14 and SEQ ID NO: 15) a *Brassica* (SEQ ID NO: 17 through SEQ ID NO: 19) and a *Simmondsia* (SEQ ID NO: 43) plant.

In yet a different embodiment of this invention, plant desaturase cDNA of at least 10 nucleotides or preferably at least 20 nucleotides and more preferably still at least 50 nucleotides, known or homologously related to known Δ-9 desaturase(s) is also provided. The cDNA encoding precursor desaturase or, alternatively, biologically active, mature desaturase is provided herein.

Methods to use nucleic acid sequences to obtain other plant desaturases are also provided. Thus, a plant desaturase may be obtained by the steps of contacting a nucleic acid sequence probe comprising nucleotides of a known desaturase sequence and recovery of DNA sequences encoding plant desaturase having hybridized with the probe.

This invention also relates to methods for obtaining plant Δ-9 desaturase by contacting an antibody specific to a known desaturase, such as *C. tinctorius* stearoyl-ACP

desaturase, with a candidate plant stearoyl-ACP desaturase under conditions conducive to the formation of an antigen:antibody immunocomplex and the recovery of the candidate plant stearoyl-ACP desaturase which reacts thereto.

In a further aspect of this invention DNA constructs comprising a first DNA sequence encoding a plant desaturase and a second DNA sequence which is not naturally found joined to said plant desaturase are provided. This invention also relates to the presence of such constructs in host cells, especially plant host cells. In yet a different aspect, this invention relates to transgenic host cells which have an expressed desaturase therein.

Constructs of this invention may contain, in the 5' to 3' direction of transcription, a transcription initiation control regulatory region capable of promoting transcription in a host cell and a DNA sequence encoding plant desaturase. Transcription initiation control regulatory regions capable of expression in prokatyotic or eukaryotic host cells are provided. Most preferred are transcription initiation control regions capable of expression in plant cells, and more preferred are transcription and translation initiation regions preferentially expressed in plant cells during the period of lipid accumulation. The DNA sequence encoding plant desaturase of this invention may be found in either the sense or anti-sense orientation to the transcription initiation control region.

Specific constructs, expression cassettes having in the 5' to 3' direction of transcription, a transcription and translation initiation control regulatory region comprising sequence immediately 5' to a structural gene preferentially expressed in plant seed during lipid accumulation, a DNA sequence encoding desaturase, and sequence 3' to the structural gene are also provided. The construct may preferably contain DNA sequences encoding plant desaturase obtainable (included obtained) from *Carthamus*, *Rininus*, *Brassica* or *Simmondsia* Δ-9 desaturase

genes. Transcription and translation initiation control regulatory regions are preferentially obtained from structural genes preferentially expressed in plant embryo tissue such as napin, seed-ACP or Bce-4.

By this invention, methods and constructs to inhibit the production of endogenous desaturase are also provided. For example, an anti-sense construct comprising, in the 5' to 3' direction of transcription, a transcription initiation control regulatory region functional in a plant cell, and an anti-sense DNA sequence encoding a portion of a plant Δ-9 desaturase may be integrated into a plant host cell to decrease desaturase levels.

In yet a different embodiment, this invention is directed to a method of producing plant desaturase in a host cell comprising the steps of growing a host cell comprising an expression cassette, which would contain in the direction of transcription, a) a transcription and translation initiation region functional in said host cell, b) the DNA sequence encoding a plant desaturase in reading frame with said initiation region, and c) and a transcript termination region functional in said host cell, under conditions which will promote the expression of the plant desaturase. Cells containing a plant desaturase as a result of the production of the plant desaturase encoding sequence and also contemplated herein.

By this invention, a method of modifying fatty acid composition in a host plant cell from a given level of fatty acid saturation to a different level of fatty acid saturation is provided by growing a host plant cell having integrated into its genome a recombinant DNA sequence encoding a plant desaturase in either a sense or anti-sense orientation under control of regulatory elements functional in said plant cell during lipid accumulation under conditions which will promote the activity of said regulatory elements. Plant cells having such a modified level of fatty acid saturation are also contemplated hereunder. Oilseeds having such a modified level of fatty

acid saturation and oils produced from such oilseeds are further provided.

DETAILED DESCRIPTION OF THE INVENTION

A plant desaturase of this invention includes any sequence of amino acids, such as a protein, polypeptide, or peptide fragment, obtainable from a plant source which is capable of catalyzing the insertion of a first double bond into a fatty acyl-ACP moiety in a plant host cell, i.e., *in vivo*, or in a plant cell-like environment, i.e. *in vitro*. "A plant cell-like environment" means that any necessary conditions are available in an environment (i.e., such factors as temperatures, pH, lack of inhibiting substances) which will permit the enzyme to function In particular, this invention relates to enzymes which add such a first double bond at the ninth carbon position in a fatty acyl-ACP chain. There may be similar plant desaturase enzymes of this invention with different specificities, such as the Δ-12 desaturase of carrot.

Nucleotide sequences encoding desaturases may be obtained from natural sources or be partially or wholly artificially synthesized. They may directly correspond to a desaturase endogenous to a natural plant source or contain modified amino acid sequences, such as sequences which have been mutated, truncated, increased or the like. Desaturases may be obtained by a variety of methods, including but not limited to, partial or homogenous purification of plant extracts, protein modeling, nucleic acid probes, antibody preparations and sequence comparisons. Typically a plant desaturase will be derived in whole or in part from a natural plant source.

Of special interest are Δ-9 desaturases which are obtainable, including those with are obtained, from *Cartharmus*, *Ricinus*, *Simmondsia*, or *Brassica*, for example *C. tinctorius*, *R. communis*, *S. chinensis* and *B. campestris*, respectively, or from plant desaturases which are obtainable through the use of these sequences. "Obtainable" refers to those desaturases which have

sufficiently similar sequences to that of the native sequences provided herein to provide a biologically active desaturase.

Once a DNA sequence which encodes a desaturase is obtained, it may be employed as a gene of interest in a nucleic acid construct or in probes in accordance with this invention. A desaturase may be produced in host cells for harvest or as a means of effecting a contact between the desaturase and its substrate. Constructs may be designed to produce desaturase in either prokaryotic or eukaryotic cells. Plant cells containing recombinant constructs encoding biologically active desaturase sequences, both expression and anti-sense constructs, as well as plants and cells containing modified levels of desaturase proteins are of special interest. For use in a plant cell, constructs may be designed which will effect an increase or a decrease in amount of endogenous desaturase available to a plant cell transformed with such a construct.

Where the target gene encodes an enzyme, such as a plant desaturase, which is already present in the host plant, there are inherent difficulties in analyzing mRNA, engineered protein or enzyme activity, and modified fatty acid composition or oil content in plant cells, especially in developing seeds; each of which can be evidence of biological activity. This is because the levels of the message, enzyme and various fatty acid species are changing rapidly during the stage where measurements are often made, and thus it can be difficult to discriminate between changes brought about by the presence of the foreign gene and those brought about by natural developmental changes in the seed. Where an expressed Δ-9 desaturase DNA sequence is derived from a plant species heterologous to the plant host into which the sequence is introduced and has a distinguishable DNA sequence, it is often possible to specifically probe for expression of the foreign gene with oligonucleotides complimentary to unique sequences of the inserted DNA/RNA. And, if the foreign gene codes for a protein with slightly different protein sequence, it may be

possible to obtain antibodies which recognize unique epitopes on the engineered protein. Such antibodies can be obtained by mixing the antiserum to the foreign protein with extract from the host plant, or with extracts containing the host plant enzyme. For example, one can isolate antibodies uniquely specific to a *C. tinctorius* Δ-9 desaturase by mixing antiserum to the desaturase with an extract containing a *Brassica* Δ-9 desaturase. Such an approach will allow the detection of *C. tinctorius* desaturase in *Brassica* plants transformed with the *C. tinctorius* desaturase gene. In plants expressing an endogenous gene in an antisense orientation, the problem is slightly different. In this case, there are no specific reagents to measure expression of a foreign protein. However, one is attempting to measure a decrease in an enzyme activity that normally is increasing during development. This makes detection of expression a simpler matter. In the final seed maturation phase, enzyme activities encoded by genes affecting oil composition usually disappear and cannot be detected in final mature seed. Analysis of the fatty acid content may be preformed by any manner known to those skilled in the art, including gas chromatography, for example.

By increasing the amount of desaturase available in the plant cell, an increased percentage of unsaturated fatty acids may be provided; by decreasing the amount of desaturase, an increased percentage of saturated fatty acids may be provided. (Modifications in the pool of fatty acids available for incorporation into triglycerides may likewise affect the composition of oils in the plant cell.) Thus, an increased expression of desaturase in a plant cell may result in increased proportion of fatty acids, such as one or more of palmitoleate (C16:1), oleate (C18:1), linoleate (C18:2) and linolenate (C18:3) are expected. Of special interest is the production of triglycerides having increased levels of oleate. Using anti-sense technology, alternatively, a decrease in the amount of desaturase available to the plant cell is expected, resulting in a

higher percentage of saturates such as one or more of laurate (C12:0), myristate (C14:0), palmitate (C16:0), stearate (C18:0), arachidate (C20:0), behemate (C22:0) and lignocerate (C24:0). Of special interest is the production of triglycerides having increased levels of stearate or palmitate and stearate. In addition, the production of a variety of ranges of such saturates is desired. Thus, plant cells having lower and higher levels of stearate fatty acids are contemplated. For example, fatty acid compositions, including oils, having a 10% level of stearate as well as compositions designed to have up to a 60% level of stearate or other such modified fatty acid(s) composition are contemplated.

The modification of fatty acid compositions may also affect the fluidity of plant membranes. Different lipid concentrations have been observed in cold-hardened plants, for example. By this invention, one may be capable of introducing traits which will lend to chill tolerance. Constitutive or temperature inducible transcription initiation regulatory control regions may have special applications for such uses.

Other applications for use of cells or plants producing desaturase may also be found. For example, potential herbicidal agents selective for plant desaturase may be obtained through screening to ultimately provide environmentally safe herbicide products. The plant desaturase can also be used in conjunction with chloroplast lysates to enhance the production and/or modify the composition of the fatty acids prepared *in vitro*. The desaturase can also be used for studying the mechanism of fatty acid formation in plants and bacteria. For these applications, constitutive promoters may find the best use.

Constructs which contain elements to provide the transcription and translation of a nucleic acid sequence of interest in a host cell are "expression cassettes". Depending upon the host, the regulatory regions will vary, including regions from structural genes from viruses, plasmid or chromosomal genes, or the like. For expression

in prokaryotic or eukaryotic microorganisms, particularly unicellular hosts, a wide variety of constitutive or regulatable promoters may be employed. Among transcriptional initiation regions which have been described are regions from bacterial and yeast hosts, such as *E. coli*, *B. subtilis*, *Saccharomyces cerevisiae*, including genes such as β-galactosidase, T7 polymerase, trp E and the like.

A recombinant construct for expression of desaturase in a plant cell ("expression cassette") will include, in the 5' to 3' direction of transcription, a transcription and translation initiation control regulatory region (the transcriptional and translational initiation regions together often also known as a "promoter") functional in a plant cell, a nucleic acid sequence encoding a plant desaturase, and a transcription termination region. Numerous transcription initiation regions are available which provide for a wide variety of constitutive or regulatable, e.g., inducible, transcription of the desaturase structural gene. Among transcriptional initiation regions used for plants are such regions associated with cauliflower mosaic viruses (35S, 19S), and structural genes such as for nopaline synthase or mannopine synthase or napin and ACP promoters, etc. The transcription/translation initiation regions corresponding to such structural genes are found immediately 5' upstream to the respective start codons. Thus, depending upon the intended use, different promoters may be desired.

Of special interest in this invention are the use of promoters which are capable of preferentially expressing the desaturase in seed tissue, in particular, at early stages of seed oil formation. Examples of such seed-specific promoters include the region immediately 5' upstream of napin or seed ACP genes, such as described in co-pending USSN 147,781, and the Bce-4 gene such as described in co-pending USSN 494,722. Alternatively, the use of the 5' regulatory region associated with an endogenous plant desaturase structural gene and/or the

transcription termination regions found immediately 3' downstream to the gene, may often be desired.

In addition, for some applications, use of more than one promoter may be desired. For example, one may design a dual promoter expression cassette each promoter having a desaturase sequence under its regulatory control. For example, the combination of an ACP and napin cassette could be useful for increased production of desaturase in a seed-specific fashion over a longer period of time than either individually.

To decrease the amount of desaturase found in a plant host cell, anti-sense constructs may be prepared and then inserted into the plant cell. By "anti-sense" is meant a DNA sequence in the 5' to 3' direction of transcription in relation to the transcription initiation region, which encodes a sequence complementary to the sequence of a native desaturase. It is preferred that an anti-sense plant desaturase sequence be complementary to a plant desaturase gene indigenous to the plant host. Sequences found in an anti-sense orientation may be found in constructs providing for transcription or transcription and translation of the DNA sequence encoding the desaturase, including expression cassettes. Constructs having more than one desaturase sequence under the control of more than one promoter or transcription initiation region may also be employed with desaturase constructs. Various transcription initiation regions may be employed. One of ordinary skill in the art can readily determine suitable regulatory regions. Care may be necessary in selecting transcription initiation regions to avoid decreasing desaturase activity in plant cells other than oilseed tissues. Any transcription initiation region capable of directing expression in a plant host which causes initiation of adequate levels of transcription selectively in storage tissues during seed development for example, should be sufficient. As such, seed specific promoters may be desired. Other manners of decreasing the amount of endogenous plant desaturase, such as ribozymes or the

screening of plant cells transformed with constructs for rare events containing sense sequences which in fact act to decrease desaturase expression, are also contemplated herein. Other analogous methods may be applied by those of ordinary skill in the art.

By careful selection of plants, transformants having particular oils profiles may be obtained. This may in part depend upon the qualities of the transcription initiation region(s) employed or may be a result of culling transformation events to exploit the variabilities of expression observed.

In order to obtain the nucleic acid sequences encoding *C. tinctorius* desaturase, a protein preparation free of a major albumin-type contaminant is required. As demonstrated more fully in the Examples, the protocols of McKeon and Stumpf, *supra*, result in a preparation contaminated with a seed storage protein. Removal of the protein contaminant may be effected by application of a reverse-phase HPLC, or alternatively, by application of a reduction and alkylation step followed by electrophoresis and blotting, for example. Other purification methods may be employed as well, now that the presence of the contaminant is confirmed and various properties thereof described. Once the purified desaturase is obtained it may be used to obtain the corresponding amino acid and/or nucleic acid sequences thereto in accordance with methods familiar to those skilled in the art. Approximately 90% of the total amino acid sequence of the *C. tinctorius* desaturase is provided in Fig. 1 and in SEQ ID NOS: 1-11. The desaturase produced in accordance with the subject invention can be used in preparing antibodies for assays for detecting plant desaturase from other sources.

A nucleic acid sequence of this invention may include genomic or cDNA sequence and mRNA. A cDNA sequence may or may not contain pre-processing sequences, such as transit peptide sequences. Transit peptide sequences facilitate the delivery of the protein to a given organelle and are

cleaved from the amino acid moiety upon entry into the organelle, releasing the "mature" sequence.

In Fig. 2 and SEQ ID NO: 13, the sequence of the *C. tinctorius* desaturase precursor protein is provided; both the transit peptide and mature protein sequence are shown. Also provided in this invention are cDNA sequences relating to *R. communis* desaturase (Fig.3 and SEQ ID NOS: 14-15), *B. campestris* desaturase (Fig. 4 and SEQ ID NOS: 17-19) and *S. chinesis* (Fig. 5 and SEQ ID NOS: 43).

The use of the precursor cDNA sequence is preferred in desaturase expression cassettes. In addition, desaturase transit peptide sequences may be employed to translocate other proteins of interest to plastid organelles for a variety of uses, including the modulation of other enzymes related to the FAS pathway. See, European Patent Application Publication No. 189,707.

As described in more detail below, the complete genomic sequence of a desaturase may be obtained by the screening of a genomic library with a desaturase cDNA probe and isolating those sequences which regulate expression in seed tissue. In this manner, the transcription, translation initiation regions and/or transcript termination regions of the desaturase may be obtained for use in a variety of DNA constructs, with or without the respective desaturase structural gene.

Other nucleic acid sequences "homologous" or "related" to DNA sequences encoding other desaturases are also provided. "Homologous" or "related" includes those nucleic acid sequences which are identical or conservatively substituted as compared to the exemplified *C. tinctorius*, *R. communis, S. chinesis* or *B. campestris* desaturase sequences of this invention or a plant desaturase which has in turn been obtained from a plant desaturase of this invention. By conservatively substituted is meant that codon substitutions encode the same amino acid, as a result of the degeneracy of the DNA code, or that a different amino acid having similar properties to the original amino acid is substituted. One skilled in the art will readily

recognize that antibody preparations, nucleic acid probes (DNA and RNA) sequences encoding and the like may be prepared and used to screen and recover desaturase from other plant sources. Typically, nucleic acid probes are labeled to allow detection, preferably with radioactivity although enzymes or other methods may also be used. For immunological screening methods, antibody preparations either monoclonal or polyclonal are utilized. Polyclonal antibodies, although less specific, typically are more useful in gene isolation. For detection, the antibody is labeled using radioactivity or any one of a variety of second antibody/enzyme conjugate systems that are commercially available. Examples of some of the available antibody detection systems are described by Oberfilder (*Focus* (1989) BRL Life Technologies, Inc., *11*:1-5).

A "homologous" or "related" nucleic acid sequence will show at least about 60% homology, and more preferably at least about 70% homology, between the known desaturase sequence and the desired candidate plant desaturase of interest, excluding any deletions which may be present. Homology is determined upon comparison of sequence information, nucleic acid or amino acid, or through hybridization reactions. Amino acid sequences are considered homologous by as little as 25% sequence identity between the two complete mature proteins. (*See generally*, Doolittle, R.F., of URFS and ORFS, University Science Books, CA, 1986.)

Oligonucleotide probes can be considerably shorter than the entire sequence, but should be at least about 10, preferably at least about 15, more preferably at least 20 nucleotides in length. When shorter length regions are used for comparison, a higher degree of sequence identity is required than for longer sequences. Shorter probes are often particularly useful for polymerase chain reactions (PCR), especially when highly conserved sequences can be identified. (*See*, Gould, *et al.*, *PNAS USA* (1989) *86*:1934-1938.) Longer oligonucleotides are also useful, up to the full length of the gene encoding the polypeptide of

interest. When longer nucleic acid fragments are employed (>100 bp) as probes, especially when using compl te or large cDNA sequences, one would screen with low stringencies (for example 40-50°C below the melting temperature of the probe) in order to obtain signal from the target sample with 20-50% deviation, i.e., homologous sequences. (*See*, Beltz, *et al.*, *Methods in Enzymology* (1983) *100*:266-285.) Both DNA and RNA probes can be used.

A genomic library prepared from the plant source of interest may be probed with conserved sequences from a known desaturase to identify homologously related sequences. Use of the entire cDNA may be employed if shorter probe sequences are not identified. Positive clones are then analyzed by restriction enzyme digestion and/or sequencing. When a genomic library is used, one or more sequences may be identified providing both the coding region, as well as the transcriptional regulatory elements of the desaturase gene from such plant source. In this general manner, one or more sequences may be identified providing both the coding region, as well as the transcriptional regulatory elements of the desaturase gene from such plant source.

In use, probes are typically labeled in a detectable manner (for example with ^{32}P-labeled or biotinylated nucleotides) and are incubated with single-stranded DNA or RNA from the plant source in which the gene is sought, although unlabeled oligonucleotides are also useful. Hybridization is detected by means of the label after single-stranded and double-stranded (hybridized) DNA or DNA/RNA have been separated, typically using nitrocellulose paper or nylon membranes. Hybridization techniques suitable for use with oligonucleotides are well known to those skilled in the art. Thus, plant desaturase genes may be isolated by various techniques from any convenient plant. Plant desaturase of developing seed obtained from other oilseed plants, such as soybean, coconut, oilseed rape, sunflower, oil palm, peanut, cocoa, cotton, corn and the like are desired as well as from non-traditional oil

sources, including but not limited to spinach chloroplast, avocado mesocarp, cuphea, California Bay, cucumber, carrot, meadowfoam, *Oenothera* and *Euglena gracillis*.

Once the desired plant desaturase sequence is obtained, it may be manipulated in a variety of ways. Where the sequence involves non-coding flanking regions, the flanking regions may be subjected to resection, mutagenesis, etc. Thus, transitions, transversions, deletions, and insertions may be performed on the naturally occurring sequence. In addition, all or part of the sequence may be synthesized, where one or more codons may be modified to provide for a modified amino acid sequence, or one or more codon mutations may be introduced to provide for a convenient restriction site or other purpose involved with construction or expression. The structural gene may be further modified by employing synthetic adapters, linkers to introduce one or more convenient restriction sites, or the like.

Recombinant constructs containing a nucleic acid sequence encoding a desaturase of this invention may be combined with other, i.e. "heterologous," DNA sequences in a variety of ways. By heterologous DNA sequences is meant any DNA sequence which is not naturally found joined to the native desaturase, including combinations of DNA sequences from the same plant of the plant desaturase which are not naturally found joined together. In a preferred embodiment, the DNA sequence encoding a plant desaturase is combined in a DNA construct having, in the 5' to 3' direction of transcription, a transcription initiation control region capable of promoting transcription in a host cell, and a DNA sequence encoding a desaturase in either a sense or anti-sense orientation. As described in more detail elsewhere, a variety of regulatory control regions containing transcriptional or transcriptional and translational regions may be employed, including all or part of the non-coding regions of the plant desaturase.

The open reading frame coding for the plant desaturase or functional fragment thereof will be joined at its 5' end

to a transcription initiation regulatory control region. In some instances, such as modulation of plant desaturase via a desaturase in an anti-sense orientation, a transcription initiation region or transcription/ translation initiation region may be used. In embodiments wherein the expression of the desaturase protein is desired in a plant host, a transcription/ translation initiation regulatory region, is needed. Additionally, modified promoters, i.e., having transcription initiation regions derived from one gene source and translation initiation regions derived from a different gene source or enhanced promoters, such as double 35S CaMV promoters, may be employed for some applications.

As described above, of particular interest are those 5' upstream non-coding regions which are obtained from genes regulated during seed maturation, particularly those preferentially expressed in plant embryo tissue, such as ACP-and napin-derived transcription initiation control regions. Such regulatory regions are active during lipid accumulation and therefore offer potential for greater control and/or effectiveness to modify the production of plant desaturase and/or modification of the fatty acid composition. Especially of interest are transcription initiation regions which are preferentially expressed in seed tissue, i.e., which are undetectable in other plant parts. For this purpose, the transcript initiation region of acyl carrier protein isolated from *B. campestris* seed and designated as "Bcg 4-4" and an unidentified gene isolated from *B. campestris* seed and designated as "Bce-4" are also of substantial interest.

Briefly, Bce4 is found in immature embryo tissue at least as early as 11 days after anthesis (flowering), peaking about 6 to 8 days later or 17-19 days post-anthesis, and becoming undetectable by 35 days post-anthesis. The timing of expression of the Bce4 gene closely follows that of lipid accumulation in seed tissue. Bce4 is primarily detected in seed embryo tissue and to a lesser extent found in the s ed coat. Bce4 has not been

detected in other plant tissues tested, root, stem and leaves.

Approximately 3.4 kb genomic sequence of Bce4 is provided in Fig. 8 and as SEQ ID NO: 27, including about 1 kb 5' to the structural gene, about 0.3 kb of the Bce4 coding gene sequence, and about 2.1 kb of the non-coding regulatory 3' sequence. Bce4 transcript initiation regions will contain at least 1 kb and more preferably about 5 to about 7.5 kb of sequence immediately 5' to the Bce4 structural gene.

The Bcg 4-4 ACP message presents a similar expression profile to that of Bce4 and, therefore, also corresponds to lipid accumulation in the seed tissue. Bcg 4-4 is not found in the seed coat and may show some differences in expression level, as compared to Bce4, when the Bcg 4-4 5' non-coding sequence is used to regulate transcription or transcription and translation of a plant stearoyl-ACP desaturase of this invention. Genomic sequence of Bcg 4-4 is provided in Fig. 9 and as SEQ ID NO: 28, including about 1.5 kb 5' to the structural gene, about 1.2 kb of the Bcg 4-4 (ACP) structural gene sequence, and about 1.3 kb of the non-coding regulatory 3' sequence.

The napin 1-2 message is found in early seed development and thus, also offers regulatory regions which can offer preferential transcriptional regulation of a desired DNA sequence of interest such as the plant desaturase DNA sequence of this invention during lipid accumulation. Napins are one of the two classes of storage proteins synthesized in developing *Brassica* embryos (Bhatty, *et al., Can J. Biochem.* (1968) *46*:1191-1197) and have been used to direct tissue-specific expression when reintroduced into the *Brassica* genome (Radke, *et al., Theor. Appl. Genet.* (1988) *75*:685-694). Genomic sequence of napin 1-2 is provided in Fig. 10 and as SEQ ID NO: 29, including about 1.7 kb 5' to the structural gene and about 1.3 kb of the non-coding regulatory 3' sequence

Regulatory transcript termination regions may be provided in DNA constructs of this invention as well.

Transcript termination regions may be provided by the DNA sequence encoding the plant desaturase or a convenient transcription termination region derived from a different gene source, especially the transcript termination region which is naturally associated with the transcript initiation region. The transcript termination region will contain at least about 1 kb, preferably about 3 kb of sequence 3' to the structural gene from which the termination region is derived.

In developing the DNA construct, the various components of the construct or fragments thereof will normally be inserted into a convenient cloning vector which is capable of replication in a bacterial host, e.g., *E. coli*. Numerous vectors exist that have been described in the literature. After each cloning, the plasmid may be isolated and subjected to further manipulation, such as restriction, insertion of new fragments, ligation, deletion, insertion, resection, etc., so as to tailor the components of the desired sequence. Once the construct has been completed, it may then be transferred to an appropriate vector for further manipulation in accordance with the manner of transformation of the host cell.

Normally, included with the DNA construct will be a structural gene having the necessary regulatory regions for expression in a host and providing for selection of transformant cells. The gene may provide for resistance to a cytotoxic agent, e.g. antibiotic, heavy metal, toxin, etc., complementation providing prototrophy to an auxotrophic host, viral immunity or the like. Depending upon the number of different host species into which the expression construct or components thereof are introduced, one or more markers may be employed, where different conditions for selection are used for the different hosts.

The manner in which the DNA construct is introduced into the plant host is not critical to this invention. Any method which provides for efficient transformation may be employed. Various methods for plant cell transformation include the use of Ti- or Ri-plasmids, microinjection,

electroporation, liposome fusion, DNA bombardment or the like. In many instances, it will be desirable to have the construct bordered on one or both sides by T-DNA, particularly having the left and right borders, more particularly the right border. This is particularly useful when the construct uses *A. tumefaciens* or *A. rhizogenes* as a mode for transformation, although the T-DNA borders may find use with other modes of transformation.

Where *Agrobacterium* is used for plant cell transformation, a vector may be used which may be introduced into the *Agrobacterium* host for homologous recombination with T-DNA or the Ti- or Ri-plasmid present in the *Agrobacterium* host. The Ti- or Ri-plasmid containing the T-DNA for recombination may be armed (capable of causing gall formation) or disarmed (incapable of causing gall formation), the latter being permissible, so long as the *vir* genes are present in the transformed *Agrobacterium* host. The armed plasmid can give a mixture of normal plant cell and gall.

A preferred method for the use of *Agrobacterium* as the vehicle for transformation of plant cells employs a vector having a broad host range replication system, at least one T-DNA boundary and the DNA sequence or sequences of interest. Commonly used vectors include pRK2 or derivatives thereof. See, for example, Ditta *et al.*, *PNAS USA*, (1980) 77:7347-7351 and EPA 0 120 515, which are incorporated herein by reference. Normally, the vector will be free of genes coding for opines, oncogenes and *vir*-genes. Included with the expression construct and the T-DNA will be one or more markers, which allow for selection of transformed *Agrobacterium* and transformed plant cells. A number of markers have been developed for use with plant cells, such as resistance to chloramphenicol, the aminoglycoside G418, hygromycin, or the like. The particular marker employed is not essential to this invention, one or another marker being preferred depending on the particular host and the manner of construction.

The expression constructs may be employed with a wide variety of plant life, particularly plant life involved in the production of vegetable oils. These plants include, but are not limited to rapeseed, sunflower, *C. tinctorius*, cotton, *Cuphea*, peanut, soybean, oil palm and corn. Anti-sense constructs may be employed in such plants which share complementarity between the endogenous sequence and the anti-sense desaturase. Of special interest is the use of an anti-sense construct having a *B. campestris* desaturase in rapeseed, including *B. campestris* and *B. napus*.

For transformation of plant cells using *Agrobacterium*, explants may be combined and incubated with the transformed *Agrobacterium* for sufficient time for transformation, the bacteria killed, and the plant cells cultured in an appropriate selective medium. Once callus forms, shoot formation can be encouraged by employing the appropriate plant hormones in accordance with known methods and the shoots transferred to rooting medium for regeneration of plants. The plants may then be grown to seed and the seed used to establish repetitive generations and for isolation of vegetable oils compositions. A variety of stable genetic lines having fixed levels of saturation may be obtained and integrated into a traditional breeding program. Hemizygous and heterozygous lines or homozygous lines may demonstrate different useful properties for oil production and/or breeding. For example, saturation levels may be increased up to 2-fold by the development of homozygous plants as compared with heterozygous (including hemizygous) plants.

The invention now being generally described, it will be more readily understood by reference to the following examples which are included for purposes of illustration only and are not intended to limit the present invention.

EXAMPLES

MATERIALS

Commercially available biological chemicals and chromatographic materials, including BSA, catalase (twice

crystalized from bovine liver), spinach ferredoxin, ferredoxin-$NADP^+$ oxidoreductase (spinach leaf), NADPH, unlabeled fatty acids, DEAE-cellulose (Whatman DE-52) CNBr-activated Sepharose 4B, and octyl-Sepharose, and Reactive Blue Agarose are from Sigma (St. Louis, MO). Triethylamine, trichloroacetic acid, guanidine-HCl, and hydrazine-hydrate are also from Sigma. Proteolytic enzymes, including endoproteinases lysC, gluC, and aspN are sequencing grade enzymes obtained from Boehringer Mannheim (Indianapolis, IN). Organic solvents, including acetone, acetonitrile, methanol, ether and petroleum ether are purchased from J.T. Baker (Phillipsburg, NJ); concentrated acids and sodium sulfate are also from J.T. Baker (Phillipsburg, NJ). HPLC grade acetonitrile and trifluoracetic acid (TFA) are obtained from Burdick and Jackson (Muskegon, MI), and from Applied Biosystems (Foster City, CA), respectively. Radiochemicals, including [9,10(n)-^{3}H] oleic acid (10mCi/μmol) and [^{3}H]-iodoacetic acid (64Ci/mol) are from New England Nuclear (Boston, MA). Phenacyl-8 Reagent (bromoacetophenone with a crown ether catalyst) used to prepare phenacyl esters of the fatty acids for analysis are from Pierce (Rockford, IL). C18 reversed-phase thin-layer chromatography plates are from Whatman (Clifton, NJ).

Acyl carrier protein (ACP) and acyl-ACP synthase are isolated from *E. coli* strain K-12 as described by Rock and Cronan (Rock and Cronan, *Methods in Enzymol* (1981) *71*:341-351 and Rock *et al.*, *Methods in Enzymol.* (1981) *72*:397-403). The *E. coli* is obtainable from Grain Processing (Iowa) as frozen late-logarithmic phase cells.

[9,10(n)-^{3}H]stearic acid is synthesized by reduction of [9,10(n)-^{3}H]oleic acid with hydrazine hydrate essentially as described by Johnson and Gurr (*Lipids* (1971) *6*:78-84). [9,10(n)-^{3}H]oleic acid (2 mCi), supplemented with 5.58mg unlabeled oleic acid to give a final specific radioactivity of 100mCi/mmol, is dissolved in 2ml of acetonitrile, acidified with 40μl of glacial acetic acid, and heated to 55°C. Reduction is initiated with 100μl of

60% (w/w) hydrazine hydrate; oxygen is bubbled through the mixture continuously. After each hour acetonitrile is added to bring the volume back to 2ml and an additional 100µl of hydrazine hydrate is added. At the end of 5 hr. the reaction is stopped by addition of 3ml of 2M HCl. The reaction products are extracted with three 3ml aliquots of petroleum ether and the combined ether extracts are washed with water, dried over sodium sulfate and evaporated to dryness. The dried reaction products are redissolved in 1.0ml acetonitrile and stored at -20°C. The distribution of fatty acid products in a 15µl aliquot is determined by preparation of phenacyl esters, which are then analyzed by thin layer chromatography on C-18 reverse phase plates developed with methanol:water:95:5 (v/v). Usually reduction to [9,10(n)-^{3}H]stearic acid is greater than 90%, a small amount of unreacted oleic acid may remain. The analysis is used to establish fraction of the total radioactivity that is present as stearate, and thereby to determine the exact substrate concentration in the enzyme assay.

Acyl-ACP substrates, including [9,10(n)-^{3}H] stearoyl-ACP are prepared and purified by the enzymatic synthesis procedure of Rock, Garwin, and Cronan (*Methods in Enzymol.* (1981) *72*:397-403).

Acyl carrier protein was covalently bound to Sepharose 4B by reaction of highly purified ACP with CNBr-activated Sepharose 4B as described by McKeon and Stumpf (*J. Biol. Chem.* (1982) *257*:12141-12147).

Example 1

In this example, an initial purification of *C. tinctorius* (safflower) desaturase, following the method of McKeon and Stumpf (*J. Biol. Chem.* (1982) *257*:12141-12142), is described.

Assay: In each of the following steps, the presence of the enzyme is detected radiometrically by measuring enzyme-catalyzed release of tritium from [9,10(n)-

^{3}H]stearoyl-ACP. Preparation of this substrate is described in "Materials" above.

The assay is performed by mixing 150µl water, 5ml dithiothreitol (100mM, freshly prepared in water), 10µl bovine serum albumin (10mg/ml in water), 15µl NADPH (25mM, freshly prepared in 0.1M Tricine-HCl, pH 8.2), 25µl spinach ferredoxin (2mg/ml Sigma Type III in water), 3µl NADPH:ferredoxin oxidoreductase (2.5 units/ml from Sigma), and 1 µl bovine liver catalase (800,000 units/ml from Sigma); after 10 min at room temperature, this mixture is added to a 13x100 mm screw-cap test tube containing 250µl sodium 1,4-piperazinediethanesulfonate (0.1M, pH 6.0). Finally, 10µl of the sample to be assayed is added and the reaction is started by adding 30µl of the substrate, [9,10(n)-^{3}H]stearoyl-ACP (100µCi/µmol, 10µM in 0.1M sodium 1,4-piperazinediethanesulfonate, pH 5.8). After sealing with a cap, the reaction is allowed to proceed for 10 min. while shaking at 23°C. The reaction is terminated by addition of 1.2ml of 5.8% tricholoracetic acid and the resulting precipitated acyl-ACP's are removed by centrifugation. The tritium released into the aqueous supernatant by the desaturase reaction is measured by liquid scintillation spectrometry. One unit of activity is defined as the amount of enzyme required to convert 1µmol of stearoyl-ACP to oleoyl-ACP, or to release 4µg-atoms of ^{3}H per minute.

Source tissue: Developing *C. tinctorius* seeds from greenhouse grown plants are harvested between 16 and 18 days after flowering, frozen in liquid nitrogen and stored at -70°C until extracted.

Acetone Powder: Approximately 50g of frozen seeds are ground in liquid nitrogen and sieved to remove large seed coat pieces to provide a fine embryo powder. The powder is washed with acetone on a Buchner funnel until all yellow color is absent from the filtrate. The powder is then air dried and further processed as described below, or may be stored frozen for at least a year at -70°C without loss of enzyme activity.

Acetone Powder Extract: The dried acetone powder is weighed and triturated with ten times its weight of 20mM potassium phosphate, pH 6.8; the mixture is then centrifuged at 12,000 x g for 20 minutes and decanted through a layer of Miracloth (Calbiochem, La Jolla, CA).

Ion Exchange Chromatography: The acetone powder extract is then applied to a DEAE-cellulose column (Whatman DE-52) (1.5 x 12 cm) equilibrated with 20mM potassium phosphate, pH 6.8. The pass-through and a wash with one column-volume (20ml) of buffer are pooled.

Affinity Chromatography: An affinity matrix for purification of the desaturase is prepared by reacting highly purified *E. coli* ACP, with CNBr-activated Sepharose 4B (Sigma). ACP (120mg) is reduced by treatment with 1mM dithiothreitol for 30 min on ice, and then desalted on Sephadex G-10 (Pharmacia) equilibrated with 0.1M sodium bicarbonate, pH 6.0. The treated ACP (20 ml, 6 mg/ml) is then mixed with 20ml of CNBr-activated Sepharose 4B swollen in 0.1M sodium bicarbonate, pH 7.0, and the mixture is allowed to stand at 4°C for one day. The gel suspension is then centrifuged, washed once with 0.1M sodium bicarbonate, pH 7.0, and then treated with 40ml 0.1M glycine, pH 8.0, for 4 hours at room temperature to block unreacted sites. The gel is then washed for five cycles with alternating 50ml volumes of 0.5M NaCl in 0.1M sodium acetate, pH 4.0, and 0.5M NaCl in 0.1M sodium bicarbonate, pH 6.5, to remove non-covalently bound ligand. The gel is loaded into a column (1.5 x 11.2 cm) and equilibrated in 20mM potassium phosphate, pH 6.8.

The combined fractions from the DE-52 column are applied to the column, which is subsequently washed with one column volume (20ml) of the equilibration buffer, and then with 2.5 column volumes (50ml) of 300mM potassium phosphate, pH 6.8. Fractions are assayed for protein using the BCA Protein Assay Reagent (Pierce, Rockford, IL) to make sure that all extraneous protein has been eluted. Active Δ-9 desaturase is eluted from the column with 600mM potassium phosphate, pH 6.8. Active fractions are analyzed

by polyacrylamide gel electrophoresis in sodium dodecyl sulfate (SDS-PAGE) on 0.75mm thick 8 x 12 cm mini-gels according to the method of Laemmli (*Nature* (1970) *227*:680). The running gel contains 10% acrylamide in a 30/0.8 ratio of acrylamide to cross-linker bis-acrylamide. Those fractions containing a predominant band at approximately 43 kD are pooled and stored frozen at -70°C until final purification. The yield from 50g of seed tissue is is approximately 60µg of protein as measured by amino acid analysis.

Further purification as described in Example 2 or Example 3 is then applied to the fractions pooled from the ACP-Sepharose column separation.

Example 2

In this example, a protocol for the final purification of *C. tinctorius* desaturase is described. Seeds are treated in accordance with Example 1.

Reverse-Phase HPLC: Fractions from the ACP-Sepharose column are pooled and applied to a Vydac C4 reverse-phase column (0.45 x 15 cm) equilibrated in 0.1% TFA, 7% acetonitrile. After a 10 min wash with 0.1% TFA, the column is eluted with a gradient of increasing acetonitrile (7%-70% v/v) in 0.1% TFA over a period of 45 min. The flow rate is 0.5ml/min throughout. Eluting components are monitored by absorbance at 214 nm. Δ-9 desaturase elutes at about 42 min. (approximately 50% acetonitrile); the major contaminant protein remaining from ACP-affinity chromatography elutes at about 28 min. (approximately 30% acetonitrile). The substantially homogeneous desaturase, which is no longer active, is identified by SDS-PAGE, in which it exhibits a single band corresponding to a molecular weight of approximately 43 kD. The quantity of desaturase protein in the sample may be determined by amino acid analysis.

Example 3

In this example, a protocol for the final purification of *C. tinctorius* desaturase is described. Seeds are treated in accordance with Example 1.

Reduction and Alkylation: Protein is precipitated out of the pooled fraction solutions recovered from the ACP-Sepharose column with 10% (w/v) trichloroacetic acid, washed with cold (-20°C) acetone, and resuspended in 1 ml 500mM Tris-HCl, pH 8.6, containing 6M guanidine-HCl, 10mM EDTA, and 3.2 mM dithiothreitol. After 2 hours, 3.52 µmol [^{3}H]-iodoacetic acid (64µCi/µmol, New England Nuclear) is added, and the reaction is allowed to proceed at room temperature in the dark for 2 hours, at which time the reaction is terminated by addition of 1µl (15µmol) ß-mercaptoethanol. The sample is then re-precipitated with 10% (w/v) trichloroacetic acid, and the pellet again washed with cold (-20°C) acetone and resuspended in Laemmli's SDS-sample buffer (*Nature* (1970) *227*:680).

SDS-Polyacrylamide Gel Electrophoresis: The resulting sample is boiled for 5 min. and then applied to a 1.5 mm thick, 8 x 12 cm, SDS-polyacrylamide mini-gel prepared as described by Laemmli, *supra*. The running gel contains 17.5% acrylamide in a 30:0.13 ratio of acrylamide to cross-linking bis-acrylamide. Separation is achieved by electrophoresis at 15 mA, for 2 hours at 4°C.

Blotting from SDS-gels to PVDF Membrane: Proteins are recovered from the gel by electroblotting at 5 mA/cm^2 to a four-layer sandwich of polyvinylidenedifluoride (PVDF) membrane for 2 h at 4°C in a buffer containing 10mM CAPS ("3-[cyclohexylamino]-1-propane-sulfonic acid"), pH 11. The membranes must be wetted in 50% methanol, prior to exposure to the blotting buffer. After blotting, the membrane layers are stained for 1-2 min. in 0.02% Coomassie Blue in 50% methanol, and then destained in 50% methanol. The desaturase is identified as a band corresponding to a molecular weight of about 43 kD; the major contaminant runs at or near the dye front of the gel corresponding to a molecular weight less than 20 kD.

The desaturase band on the PVDF membrane may be applied directly to the Edman sequencer (Applied Biosystems Model 477A) for determination of the N-terminal sequence of the intact protein, or for more extensive sequence determination, may be eluted from the membrane in 40% acetonitrile to recover pure desaturase in solution. Acetonitrile is removed from the eluted desaturase by evaporation on a Speed-Vac (Savant; Farmingdale, NY), and the substantially homogeneous Δ-9 desaturase is resuspended in an appropriate buffer for subsequent proteolytic digestion as described in Example 4. The quantity of desaturase protein present may be determined by amino acid analysis.

Alternatively, if the sample is to be digested with trypsin or gluC protease to generate peptides for amino acid sequence analysis, proteins may be electroblotted to nitrocellulose membranes and stained with Ponceau or amido black.

Example 4

In this example, a method for the determination of the amino acid sequence of a desaturase is described.

Reduction and Alkylation: Substantially homogenous stearoyl-ACP desaturase (See, Example 2) is reduced and alkylated with [^{3}H]-iodacetic acid (See, Example 3), except that the final acetone-washed pellet is resuspended in the appropriate buffer for subsequent proteolysis. Reduction and alkylation assures complete denaturation of the protein so that complete proteolysis can occur. The sample may be alkylated with radiolabeled iodoacetamide or with 4-vinylpyridine instead of [^{3}H]-iodacetic acid in substantially the same manner. Use of iodoacetic acid affords an alkylated sample with greater solubility, which is advantageous in subsequent sample manipulation.

Proteolysis: Substantially pure alkylated samples are digested with endoproteinase lysC. The sample is resuspended in 100 µl of 25 mM Tris-HCl, pH 8.8, containing 1 mM EDTA. Endoproteinase lysC is added to the sample in a

protease/desaturase ratio of 1/50 (w/w). Digestion is allowed to proceed at room temperature for 8 hours, at which time another equal amount of protease is added. After 18 more hours, 1 µl of concentrated HCl is added to stop proteolysis, and the sample is applied directly to a Vydac C18 reverse-phase column (0.2 x 15 cm) equilibrated in 7% acetonitrile (v/v) in 0.1 mM sodium phosphate, pH 2.2. After washing for 20 min with the equilibration buffer, peptides are eluted with a gradient in acetonitrile (7-70%, v/v) over 120 min. Flow rate is 50 µl/min, throughout. Eluting components are monitored by absorbance at 214 nm, and individual peptide peaks are collected as separate fractions. The peptide fractions are further purified by application to a second Vydac C18 reverse-phase column (0.2 x 15 cm) equilibrated in 7% (v/v) acetonitrile in 0.1% (v/v) trifluoroacetic acid. Again, after a 20 min wash with equilibration buffer, the substantially pure peptides are eluted with a gradient (7-70%, v/v) of acetonitrile in 0.1% trifluoroacetic acid over 120 min. The flow rate is 50 µl/min, throughout. Eluting components are monitored by absorbance at 214 nm, and individual peptide peaks are collected as separate fractions. These substantially pure peptides are applied directly to the Edman sequencer (Applied Biosystems, Model 477A) for amino acid sequence analysis. Alternatively, peptide fraction from the first HPLC purification in phosphate buffer, or from a single chromatography step in trifluoroacetic acid buffer, may be applied directly to the sequencer, but these fractions, in many cases, are not substantially pure and yield mixed or ambiguous sequence information.

Other proteases may be used to digest desaturase, including but not limited to trypsin, gluC, and aspN. While the individual digest buffer conditions may be different, the protocols for digestion, peptide separation, purification, and sequencing are substantially the same as those outlined for the digestion with lysC. Alternatively, desaturase may be digested chemically using cyanogen bromide (Gross *Methods Enzymol* (1967) *11*:238-255 or Gross

and Witkop *J. Am. Chem. Soc.* (1961) *83*:1510), hydroxylamine (Bornstein and Balian *Methods Enzymol.* (1977) *47*:132-745), iodosobenzoic acid (Inglis *Methods Enzymol.* (1983) *91*:324-332), or mild acid (Fontana *et al.*, *Methods Enzymol.* (1983) *91*:311-317), as described in the respective references.

Fragments generated from these digestion steps of *C. tinctorius* desaturase are presented in Fig. 1 and as SEQ ID NOS: 1-11.

Example 5

In this example, the preparation of a plant embryo cDNA bank, using the methods as described in Alexander, *et al.* (*Methods in Enzymology* (1987) *154*:41-64) and the screening of the bank to obtain a desaturase cDNA clone is described.

C. tinctorius: A plant embryo cDNA library may be constructed from poly(A)+ RNA isolated from *C. tinctorius* embryos collected at 14-17 days post-anthesis. Poly(A)+ RNA is isolated from polyribosomes by a method initially described by Jackson and Larkins (*Plant Physiol.* (1976) *57*:5-10) as modified by Goldberg *et al.* (*Developmental Biol.* (1981) *83*:201-217).

The plasmid cloning vector pCGN1703, derived from the commercial cloning vector Bluescribe M13- (Stratagene Cloning Systems; San Diego, CA), is made as follows. The polylinker of Bluescribe M13- is altered by digestion with *Bam*HI, treatment with mung bean endonuclease, and blunt-end ligation to create a *Bam*HI-deleted plasmid, pCGN1700. pCGN1700 is digested with *Eco*RI and *Sst*I (adjacent restriction sites) and annealed with synthetic complementary oligonucleotides having the sequences 5' CGGATCCACTGCAGTCTAGAGGGCCCGGGA 3'(SEQ ID NO: 30) and 5' AATTTCCCGGGCCCTCTAGACTGCAGTGGATCCGAGCT 3' (SEQ ID NO: 31). These sequences are inserted to eliminate the *Eco*RI site, move the *Bam*HI site onto the opposite side of the *Sst*I (also, sometimes referred to as "*Sac*I" herein) site found in Bluescribe, and to include new restriction sites *Pst*I, *Xba*I, *Apa*I, *Sma*I. The resulting plasmid pCGN1702, is

digested with *Hin*dIII and blunt- nded with Klenow enzyme; the linear DNA is partially digested with *Pvu*II and ligated with T4 DNA ligase in dilute solution. A transformant having the *lac* promoter region deleted is selected (pCGN1703) and is used as the plasmid cloning vector.

Briefly, the cloning method for cDNA synthesis is as follows. The plasmid cloning vector is digested with *Sst*I and homopolymer T-tails are generated on the resulting 3'-overhang sticky-ends using terminal deoxynucleotidyl transferase. The tailed plasmid is separated from undigested or un-tailed plasmid by oligo(dA)-cellulose chromatography. The resultant vector serves as the primer for synthesis of cDNA first strands covalently attached to either end of the vector plasmid. The cDNA-mRNA-vector complexes are treated with terminal transferase in the presence of deoxyguanosine triphosphate, generating G-tails at the ends of the cDNA strands. The extra cDNA-mRNA complex, adjacent to the *Bam*HI site, is removed by *Bam*HI digestion, leaving a cDNA-mRNA-vector complex with a *Bam*HI sticky-end at one end and a G-tail at the other. This complex is cyclized using the annealed synthetic cyclizing linker, 5'-GATCCGCGGCCGCGAATTCGAGCTCCCCCCCCCC-3' and

3'-GCGCCGGCGCTTAAGCTCGA-5'

which has a *Bam*HI sticky-end and a C-tail end. Following ligation and repair the circular complexes are transformed into *E. coli* strain DH5α (BRL; Gaithersburg, MD) to generate the cDNA library. The *C. tinctorius* embryo cDNA bank contains between 3×10^6 and 5×10^6 clones with an average cDNA insert size of approximately 1000 base pairs.

Probe production Including PCR Reactions: Two regions of amino acid sequence (Example 4) with low codon degeneracy are chosen from opposite ends of peptide sequence "Fragment F2" (SEQ ID NO:2) for production of a probe for the plant desaturase cDNA. Two sets of mixed oligonucleotides are designed and synthesized for use as forward (SEQ ID NOS: 21-24) and reverse (SEQ ID NOS: 25-26) primers, respectively, in the polymerase chain reaction

(Saiki *et al.*, *Science* (1985) *230*:1350-1354; Oste, *Biotechniques* (1988) *6*:162-167). See, Fig. 6. All oligonucleotides are synthesized on an Applied Biosystems 380A DNA synthesizer.

Probes to *C. tinctorius* desaturase may be prepared using the peptide sequence "Fragment 2" (SEQ ID NO: 2) identified in Fig. 1. Four types of forward primers were synthesized and labeled 13-1, 13-2, 13-3, and 13-4 (SEQ ID NOS: 21-24, respectively). Two groups of reverse primers were synthesized and designated 13-5A and 13-6A (SEQ ID NOS: 25-26, respectively). The primer sequences are shown in Fig. 6. These oligonucleotide groups have a redundancy of 64 or less and contain either 20 or 17 bases of coding sequence along with flanking restriction site sequences for *Hin*dIII or *Eco*RI. Based on the intervening amino acid sequence between the primer regions on peptide "Fragment 2" (SEQ ID NO: 2) the PCR product is expected to contain 107 base pairs.

Polymerase chain reaction is performed using the cDNA library DNA as template and the possible eight combinations of the four forward and two reverse oligonucleotides as primers in a Perkin-Elmer/Cetus DNA Thermal Cycler (Norwalk, CT) thermocycle file 1 min. 94°C, 2 min. 42°C, 2 min rise from 42°-72°C for 30 cycles, followed by the step cycle file without step rises, 1 min. 94°C, 2 min. 42°C, 3 min. 72°C with increasing 15 sec extensions of the 72°C step for 10 cycles, and a final 10 min. 72°C extension.

The product of the 13-4 forward primer (SEQ ID NO: 24) and the 13-5A reverse primer (SEQ ID NO: 25) reaction was ethanol precipitated and then digested with *Hin*dIII and *Eco*RI, the resulting fragment was subcloned into pUC8 (Vieira and Messing, *Gene* (1982) *19*:259-268). Minipreparation DNA (Maniatis *et al.*, *Molecular_Cloning: A Laboratory Manual* (1982) Cold Harbor Laboratory, New York) of one clone was sequenced by Sanger dideoxy sequencing (Sanger *et al.*, *Proc. Nat. Acad. Sci. USA* (1977) *74*:5463-5467) using the M13 universal and reverse primers. Translation of the resulting DNA sequence results in a

peptide sequence that exactly matches the amino acid sequence in peptide "Fragment F2" (SEQ ID NO: 2).

An exact 50 base oligonucleotide designated DESAT-50 is synthesized to match the sequence of the PCR reaction product from the first valine residue to the last tyrosine residue.

The probe DSAT-50 5' - GTAAGTAGGTAGGGCTTCCTCTGTAATCATATCTCCAACCAAAACAACAA -3' (SEQ ID NO: 32) is used to probe the *C. tinctorius* embryo cDNA library.

Library screen

The *C. tinctorius* embryo cDNA bank is moved into the cloning vector lambda gt10 (Stratagene Cloning Systems) by digestion of total cDNA with *Eco*RI and ligation to lambda gt10 DNA digested with *Eco*RI. The titer of the resulting library was ~5x10^5/ml. The library is then plated on *E. coli* strain C600 (Huynh, *et al.*, *DNA Cloning Vol. 1* Eds. Glover D.M. IRL Press Limited: Oxford England, pp. 56, 110) at a density of 5000 plaques/150 mm NZY ("NZYM" as defined in Maniatis *et al. supra*) agar plate to provide over 45,000 plaques for screening. Duplicate lifts are taken of the plaques using NEN Colony Plaque Screen filters by laying precut filters over the plates for ~1 minute and then peeling them off. The phage DNA is immobilized by floating the filters on denaturing solution (1.5M NaCl, .05M NaOH) for 1 min., transferring the filters to neutralizing solution (1.5M NaCl, 0.5M Tris-HCI pH 8.0) for 2 min. and then to 2XSSC (1xSSC = 0.15M NaCl; 0.015M Na citrate) for 3 min., followed by air drying. The filters are hybridized with ^{32}P end-labeled DSAT-50 oligonucleotide (SEQ ID NO: 32) (BRL 5' DNA Terminus Labeling System) by the method of Devlin et al., (*DNA* (1988) 7:499-807) at 42° C overnight, and washed for 30 min. at 50°C in 2XSSC, 0.5% SDS and then twice for 20 min. each at 50°C in 0.1XSSC, 0.5% SDS. Filters are exposed to X-ray film at -70°C with a Dupont Cronex intensifying screen for 48 hours.

Clones are detected by hybridization with the DSAT-50 oligonucleotide and plaque purified. The complete nucleotide sequence (SEQ ID NO: 12) of the cDNA insert of a clone, pCGN2754, and a partial restriction map thereof are presented in Figures 2 and 7A, respectively. The cDNA insert includes 1533 bases plus a poly(A) track at the 3' end of 100-200 bases. The open reading frame for the desaturase begins at the first ATG (nucleotide 106) from the 5' end and stops at nucleotide 1294. The translated amino acid sequence is presented in Fig. 2 and SEQ ID NO: 13. The open reading frame includes a 33 amino acid transit peptide not found in the amino acid sequence of the mature protein. The N-terminus of the protein begins at the alanine immediately following the *Nco*I site (nucleotide 202) indicating the site of the transit peptide processing.

Example 6

In this example, expression of a plant desaturase in a prokaryote is described.

Desaturase expression construct in E. coli

A plasmid for expression of desaturase activity in *E. coli* is constructed as follows. The desaturase cDNA clone pCGN2754 is digested with *Hin*dIII and SalI and ligated to pCGN2016 (a chloramphenicol resistant version of Bluescript KS-) digested with *Hin*dIII and *Xho*I. The resulting plasmid is pCGN1894.

pCGN2016 is prepared by digesting pCGN565 with *Hha*I, and the fragment containing the chloramphenicol resistance gene is excised, blunted by use of mung bean nuclease, and inserted into the *Eco*RV site of Bluescript KS- (Stratagene: La Jolla, CA) to create pCGN2008. The choramphenicol resistance gene of pCGN2008 is removed by *Eco*RI/*Hin*dIII digestion. After treatment with Klenow enzyme to blunt the ends, the fragment is ligated to *Dra*I digested Bluescript KS-. A clone that has the *Dra*I fragment containing ampicillin resistance replaced with the chloramphenicol resistance is chosen and named pCGN2016.

pCGN565 is a cloning vector based on pUC12-cm (K. Buckley Ph.D. Thesis, Regulation and expression of the phi X174 lysis gene, University of California, San Diego, 1985), but contains pUC18 linkers (Yanisch-Perron, *et al.*, *Gene* (1985) *53*:103-119).

The fragment containing the mature coding region of the Δ-9 desaturase, 3'-noncoding sequences and poly(A) tails is subcloned from pCGN1894 digested with *Nco*1 and *Asp*718 into pUC120, an *E. coli* expression vector based on pUC118 (Vieira and Messing, *Methods in Enzymology* (1987) *153*:3-11) with the lac region inserted in the opposite orientation and an *Nco*I site at the ATG of the lac peptide (Vieira, J. PhD. Thesis, University of Minnesota, 1988). The *E. coli* desaturase expression plasmid is designated pCGN3201. The desaturase sequences are inserted such that they are aligned with the lac transcription and translation signals.

Expression of Desaturase in E.coli

Single colonies of *E. coli* strain 7118 (Maniatis *et al.*, *supra*) containing pUC120 or pCGN3201 are cultured in 80 mls each of ECLB broth, 300 mg/L penicillin. The cells are induced by the addition of 1mM IPTG. Cells are grown overnight (18 hrs) at 37° C.

Eighty mls of overnight cultures of *E. coli* (induced and uninduced) containing pUC120 or pCGN3201 are centrifuged at 14,800 x g for 15 min. The pelleted cells are resuspended in 3 mls 20 mM phosphate buffer, pH 6.8. Resuspended cells were broken in a french press at 16,000 psi. Broken cell mixtures are centrifuged 5000xg for 5 min. 100 µl of each supernatant is applied to a G-25 Sephadex gel filtration centrifugal column (Boehringer Mannheim Biochemicals), equilibrated in 20mM phosphate buffer pH 6.8. Columns are spun for 4 min at 5000xg. Effluent was collected and used as enzyme source in the desaturase assay.

Desaturase activity is assayed as described in Example 1. Both pUC120-containing, IPTG-induced cells and uninduced cells do not express detectable stearoyl-ACP

desaturase activity. The pCGN3201 IPTG-induced extract contains 8.22 nmol/min of desaturase activity. pCGN3201 uninduced extracts contains 6.45 nmol/min of activity. The pCGN3201 IPTG-induced extract shows 21.5% more activity than the uninduced pCGN3201 extract.

Detection of induced protein in E. coli.

Extracts of overnight cultures of *E. coli* strain 7118 (Maniatis *et al. supra*) containing pCGN3201 or pUC120 grown in ECLB containing 300 mg/L penicillin induced with 1mM IPTG are prepared as follows. 1.5 ml of overnight culture grown shaking at 37°C are pelleted in Eppendorf tubes for 10 min at 10-13,000 µg. Pellets are resuspended in 150 ul SDS sample buffer (0.05M Tris-HCl, pH6.8, 1% SDS, 5% ß-mercaptoethanol, 10% glycerol and 0.005% bromophenol blue) and boiled for 10 min. 25 µl of each sample are electrophoresed on a 10% polyacrylamide gel (Laemmli, *Nature* (1970) *227*:680) at 25 mA for 5 hours. Gels are stained in 0.05% Coomassie Brilliant Blue, 25% isopropanol and 10% acetic acid and destained in 10% acetic acid and 10% isopropanol. A band is detected at a position just below the 43,000 MW protein marker (SDS PAGE standard, Low molecular weight, BioRad, Richmond CA) in the pCGN3201 extracts that is not present in the pUC120 extracts. This is the approximate molecular weight of mature desaturase protein.

Requirement for Spinach Ferredoxin

Stearoyl-ACP desaturase can also be expressed in *E. coli* by subcloning into the *E. coli* expression vector pET8c (Studier, *et al.*, *Methods Enzymol*. (1990) *185*:60-89). The mature coding region (plus an extra Met codon) of the desaturase cDNA with accompanying 3'-sequences is inserted as an *Nco*1 - *Sma* 1 fragment into pET8c at the *Nco*1 and *Bam*H1 sites (after treatment of the *Bam*H1 site with Klenow fragment of DNA polymerase to create a blunt end) to create pCGN3208. The plasmid pCGN3208 is maintained in *E. coli* strain BL21(DE3) which contains the T7 polymerase gene

under the control of the isopropyl-b-D-thiogalactopyranoside (IPTG)-inducible *lac*UV5 promoter (Studier *et al., supra*).

E. coli cells containing pCGN3208 are grown at 37°C to an OD595 of ~0.7 in NZY broth containing 0.4% (w/v) glucose and 300 mg/liter penicillin, and then induced for 3 hours with 0.4 mM IPTG. Cells are pelleted from 1 ml of culture, dissolved in 125 µl of SDS sample buffer (10) and heated to 100°C for 10 min. Samples are analyzed by SDS polyacrylamide gel electrophoresis at 25 mA for 5 h. Gels are stained in 0.05% Coomassie Brilliant Blue, 25% (v/v) isopropanol and 10% (v/v) acetic acid. A band is detected at a position just below the 43,000 MW protein marker (SDS PAGE standard, Low Molecular Weight, BioRad, Richmond, CA) in the pCGN3208 extract that is not present in the pET8c extracts. This is the approximate molecular weight of mature desaturase protein.

For activity assays, cells are treated as described above and extracts are used as enzyme source in the stearoyl-ACP desaturase assay as described in Example 1. The extract from IPTG-induced pCGN3208 cells contains 8.61 nmol/min/mg protein of desaturase activity. The extract from pCGN3208 uninduced cells contains 1.41 nmol/min/mg protein of desaturase activity. The extract from pCGN3208 induced cells, thus has approximately 6-fold greater activity than the extract from uninduced pCGN3208 cells. Extracts from both induced and uninduced cells of pET8c do not contain detectable stearoyl-ACP desaturase activity.

Samples are also assayed as described in Example 1, but without the addition of spinach ferredoxin, to determine if the *E. coli* ferredoxin is an efficient electron donor for the desaturase reaction. Minimal activity is detected in *E. coli* extracts unless spinach ferredoxin is added exogenously.

Example 7

In this example, the preparation of an ACP expression cassette containing a plant desaturase in a binary vector suitable for plant transformation is described.

ACP Expression Cassette

An expression cassette utilizing 5'-upstream sequences and 3'-downstream sequences obtainable from *B. campestris* ACP gene can be constructed as follows.

A 1.45kb *Xho*I fragment of Bcg 4-4 (Fig. 9 and SEQ ID NO: 28) containing 5'-upstream sequences is subcloned into the cloning/sequencing vector Bluescript+ (Stratagene Cloning Systems, San Diego, CA). The resulting construct, pCGN1941, is digested with *Xho*I and ligated to a chloramphenicol resistant Bluescript M13+ vector, pCGN2015 digested with *Xho*I. pCGN2015 is prepared as described for pCGN2016 (See, Example 6) except that the *Eco*RI/*Hin*dIII "chloramphenicol" fragment isolated from pCGN2008 is ligated with the 2273 bp fragment of Bluescript KS^+ (Stratagene; LaJolla, CA) isolated after digestion with *Dra*I. This alters the antibiotic resistance of the plasmid from penicillin resistance to chloramphenicol resistance. The chloramphenicol resistant plasmid is pCGN1953.

3'-sequences of Bcg 4-4 are contained on an *Sst*I/BglII fragment cloned in the *Sst*I/*Bam*HI sites of M13 Bluescript+ vector. This plasmid is named pCGN1940. pCGN1940 is modified by *in vitro* site-directed mutagenesis (Adelman *et al.*, *DNA* (1983) *2*:183-193) using the synthetic oligonucleotide 5'-CTTAAGAAGTAACCCGGGCTGCAGTTTTAGTATTAAGAG-3' (SEQ ID NO: 33) to insert *Sma*I and *Pst*I restriction sites immediately following the stop codon of the reading frame for the ACP gene 18 nucleotides from the *Sst*I site. The 3'-noncoding sequences from this modified plasmid, pCGN1950, are moved as a *PsI-Sma*I fragment into pCGN1953 cut with *Pst*I and *Sma*I. The resulting plasmid pCGN1977 comprises the ACP expression cassette with the unique restriction sites *Eco*RV, *Eco*RI and *Pst*I available between the 1.45kb 5' and 1.5 kb of 3'-noncoding sequences (SEQ ID

NO: 28) for the cloning of genes to be expressed under regulation of these ACP gene regions.

Desaturase Expression in Plants

Desaturase cDNA sequences from pCGN2754 are inserted in the ACP expression cassette, pCGN1977, as follows. pCGN2754 is digested with *Hin*dIII (located 160 nucleotides upstream of the start codon) and *Asp*718 located in the polylinker outside the poly (A) tails. The fragment containing the coding region for desaturase was blunt-ended using DNA polymerase I and ligated to pCGN1977 digested with *Eco*RV. A clone containing the desaturase sequences in the sense orientation with respect to the ACP promoter is selected and called pCGN1895. This expression cassette may be inserted into a binary vector, for example, for *Agrobacterium*-mediated transformation, or employed in other plant transformation techniques.

Binary Vector and Agrobacterium Transformation

The fragment containing the pCGN1895 expression sequences ACP 5'/desaturase/ACP 3' is cloned into a binary vector pCGN1557 (described below) for *Agrobacterium* transformation by digestion with Asp718 and XbaI and ligation to pCGN1557 digested with Asp718 and XbaI. The resulting binary vector is called pCGN1898.

pCGN1898 is transformed into *Agrobacterium tumefaciens* strain EHA101 (Hood, *et al., J. Bacteriol.* (1986) *168*:1291-1301) as per the method of Holsters, *et al., Mol. Gen. Genet.* (1978) *163*:181-187.

RNA blot analysis of seeds (T2) from T1 plants show the presence of a mRNA species for the inserted *C. tinctorius* desaturase, but the amount of message is low compared to endogenous levels of mRNA for the *Brassica* desaturase, suggesting that the expression levels were insufficient to significantly increase the amount of desaturase enzyme above that normally present. This is consistent with the negative results from oil, desaturase activity and Western blot analyses.

Construction of pCGN1557

pCGN1557 (McBride and Summerfelt, *Plant Molecular Biology* (1990) *14(2)*:269-276) is a binary plant transformation vector containing the left and right T-DNA borders of *Agrobacterium tumefaciens* octopine Ti-plasmid pTiA6 (Currier and Nester, *supra*, the gentamycin resistance gene of pPH1JI (Hirsch and Beringer, *supra*), an *Agrobacterium rhizogenes* Ri plasmid origin of replication from pLJbB11 (Jouanin *et al.*, *supra*), a 35S promoter-kanR-tml3' region capable of conferring kanamycin resistance to transformed plants, a ColE1 origin of replication from pBR322 (Bolivar *et al.*, *supra*), and a *lacZ*' screenable marker gene from pUC18 (Yanish-Perron *et al.*, *supra*).

There are three major intermediate constructs used to generate pCGN1557:

pCGN1532 (see below) contains the pCGN1557 backbone, the pRi plasmid origin of replication, and the ColE1 origin of replication.

pCGN1546 (see below) contains the CaMV35S5'-kan^R-tml3' plant selectable marker region.

pCGN1541b (see below) contains the right and left T-DNA borders of the *A. tumefaciens* octopine Ti-plasmid and the *lacZ*' region from pUC19.

To construct pCGN1557 from the above plasmids, pCGN1546 is digested with *Xho*I, and the fragment containing the CaMV 35S5'-kan^R-tml3' region is cloned into the *Xho*I site of pCGN1541b to give the plasmid pCGN1553, which contains T-DNA/left border/CaMV 35S5'-kanR-tml3'/*lacZ*'/T-DNA left border. pCGN1553 is digested with *Bgl*II, and the fragment containing the T-DNA/left border/CaMV35S5'-kan^R-tml3'/*lacZ*'/T-DNA left border region is ligated into *Bam*HI-digested pCGN1532 to give the complete binary vector, pCGN1557.

pCGN1532

The 3.5kb *Eco*RI-*Pst*I fragment containing the gentamycin resistance gene is removed from pPh1JI (Hirsch and Beringer, *Plasmid* (1984) *12*:139-141) by *Eco*RI-*Pst*I

dig stion and cloned into *Eco*RI-*Pst*I digested pUC9 (Vieira and Messing, *Gene* (1982) *19*:259-268) to generate pCGN549. *Hin*dIII-*Pst*I digestion of pCGN549 yields a 3.1 kb fragment bearing the gentamycin resistance gene, which is made blunt ended by the Klenow fragment of DNA polymerase I and cloned into *Pvu*II digested pBR322 (Bolivar *et al., Gene* (1977) *2*:95-113) to create pBR322Gm. pBR322Gm is digested with *Dra*I and *Sph*I, treated with Klenow enzyme to create blunt ends, and the 2.8 kb fragment cloned into the Ri origin-containing plasmid pLJbB11 (Jouanin *et al., Mol. Gen. Genet.* (1985) *201*:370-374) which has been digested with *Apa*I and made blunt-ended with Klenow enzyme, creating pLHbB11Gm. The extra ColE1 origin and the kanamycin resistance gene are deleted from pLHbB11Gm by digestion with *Bam*HI followed by self closure to create pGmB11. The *Hin*dII site of pGmB11 is deleted by *Hin*dIII digestion followed by treatment with Klenow enzyme and self closure, creating pGmB11-H. The *Pst*I site of pGmB11-H is deleted by *Pst*I digestion followed by treatment with Klenow enzyme and self closure, creating pCGN1532.

<u>Construction of pCGN1546</u>

The 35S promoter-tml3' expression cassette, pCGN986, contains a cauliflower mosaic virus 35S (CaMV35) promoter and a T-DNA tml 3'-region with multiple restriction sites between them. pCGN986 is derived from another cassette, pCGN206, containing a CaMV35S promoter and a different 3' region, the CaMV region VI 3'-end. The CaMV 35S promoter is cloned as an *Alu*I fragment (bp 7144-7734) (Gardner *et. al., Nucl. Acids Res.* (1981) *9*:2871-2888) into the *Hinc*II site of M13mp7 (Messing, *et. al., Nucl. Acids Res.* (1981) *9*:309-321) to create C614. An *Eco*RI digest of C614 produced the *Eco*RI fragment from C614 containing the 35S promoter which is cloned into the *Eco*RI site of pUC8 (Vieira and Messing, *Gene* (1982) *19*:259) to produce pCGN147.

pCGN148a containing a promoter region, selectable marker (KAN with 2 ATG's) and 3' region, is prepared by

digesting pCGN528 with *Bgl*II and inserting the *Bam*HI-*Bgl*II promoter fragment from pCGN147. This fragment is cloned into the *Bgl*II site of pCGN528 so that the *Bgl*II site is proximal to the kanamycin gene of pCGN528.

The shuttle vector used for this construct pCGN528, is made as follows: pCGN525 is made by digesting a plasmid containing Tn5 which harbors a kanamycin gene (Jorgenson *et. al., Mol. Gen. Genet.* (1979) *177*:65) with *Hin*dIII-*Bam*HI and inserting the *Hin*dIII-*Bam*HI fragment containing the kanamycin gene into the *Hin*dIII-*Bam*HI sites in the tetracycline gene of pACYC184 (Chang and Cohen, *J. Bacteriol.* (1978) *134*:1141-1156). pCGN526 was made by inserting the *Bam*HI fragment 19 of pTiA6 (Thomashow *et. al., Cell* (1980) *19*:729-739), modified with *Xho*I linkers inserted into the *Sma*I site, into the *Bam*HI site of pCGN525. pCGN528 is obtained by deleting the small *Xho*I fragment from pCGN526 by digesting with *Xho*I and religating.

pCGN149a is made by cloning the *Bam*HI-kanamycin gene fragment from pMB9KanXXI into the *Bam*HI site of pCGN148a. pMB9KanXXI is a pUC4K variant (Vieira and Messing, *Gene* (1982) *19*:259-268) which has the *Xho*I site missing, but contains a functional kanamycin gene from Tn903 to allow for efficient selection in *Agrobacterium*.

pCGN149a is digested with *Hin*dIII and *Bam*HI and ligated to pUC8 digested with *Hin*dIII and *Bam*HI to produce pCGN169. This removes the Tn903 kanamycin marker. pCGN565 (see pCGN2016 description) and pCGN169 are both digested with *Hin*dIII and *Pst*I and ligated to form pCGN203, a plasmid containing the CaMV 35S promoter and part of the 5'-end of the Tn5 kanamycin gene (up to the *Pst*I site, Jorgenson *et. al.*, (1979), *supra*). A 3'-regulatory region is added to pCGN203 from pCGN204 (an *Eco*RI fragment of CaMV (bp 408-6105) containing the region VI 3' cloned into pUC18 (Yanisch-Perron, *et al.*, *Gene* (1985) *33*:103-119) by digestion with *Hin*dIII and *Pst*I and ligation. The resulting cassette, pCGN206, is the basis for the construction of pCGN986.

The pTiA6 T-DNA tml 3'-sequences are subcloned from the *Bam*19 T-DNA fragment (Thomashow *et al.*, (1980) *supra*) as a *Bam*HI-*Eco*RI fragment (nucleotides 9062 to 12,823, numbering as in Barker *et al.*, *Plant Mol. Biol.* (1982) *2*:335-350) and combined with the pACYC184 (Chang and Cohen (1978), *supra*) origin of replication as an *Eco*RI-*Hin*dIII fragment and a gentamycin resistance marker (from plasmid pLB41), obtained from D. Figurski) as a *Bam*HI-*Hin*dIII fragment to produce pCGN417.

The unique *Sma*I site of pCGN417 (nucleotide 11,207 of the *Bam*19 fragment) is changed to a *Sac*I site using linkers and the *Bam*HI-*Sac*I fragment is subcloned into pCGN565 to give pCGN971. The *Bam*HI site of pCGN971 is changed to an *Eco*RI site using linkers. The resulting *Eco*RI-*Sac*I fragment containing the tml 3' regulatory sequences is joined to pCGN206 by digestion with *Eco*RI and *Sac*I to give pCGN975. The small part of the Tn5 kanamycin resistance gene is deleted from the 3'-end of the CaMV 35S promoter by digestion with *Sal*I and *Bgl*II, blunting the ends and ligation with *Sal*I linkers. The final expression cassette pCGN986 contains the CaMV 35S promoter followed by two *Sal*I sites, an *Xba*I site, *Bam*HI, *Sma*I, *Kpn*I and the tml 3' region (nucleotides 11207-9023 of the T-DNA).

The 35S promoter-tml 3' expression cassette, pCGN986 is digested with *Hin*dIII. The ends are filled in with Klenow polymerase and *Xho*I linkers added. The resulting plasmid is called pCGN986X. The *Bam*HI-*Sac*I fragment of pBRX25 (see below) containing the nitrilase gene is inserted into *Bam*HI-*Sac*I digested pCGN986X yielding pBRX66.

Construction of pBRX25 is described in U.S. Letters Patent 4,810,648, which is hereby incorporated by reference. Briefly, the method is as follows: The nucleotide sequence of a 1212-bp *Pst*I-*Hinc*II DNA segment encoding the bromoxynil-specific nitrilase contains 65-bp of 5' untranslated nucleotides. To facilitate removal of a portion of these excess nucleotides, plasmid pBRX9 is digested with *Pst*I, and treated with nuclease *Bal*31. *Bam*HI linkers are added to the resulting ends. *Bam*HI-*Hinc*II

fragments containing a functional bromoxynil gene are cloned into the *Bam*HI-*Sma*I sites of pCGN565. The resulting plasmid, pBRX25, contains only 11 bp of 5' untranslated bacterial sequence.

pBRX66 is digested with *Pst*I and *Eco*RI, blunt ends generated by treatment with Klenow polymerase, and *Xho*I linkers added. The resulting plasmid pBRX68 now has a tml 3' region that is approximately 1.1kb. pBRX68 is digested with *Sal*I and *Sac*I, blunt ends generated by treatment with Klenow polymerase and *Eco*RI linkers added. The resulting plasmid, pCGN986XE is a 35S promoter - tml 3' expression cassette lacking the nitrilase gene.

The Tn5 kanamycin resistance gene is then inserted into pCGN986XE. The 1.0 kb *Eco*RI fragment of pCGN1536 (see pCGN1547 description) is ligated into pCGN986XE digested with *Eco*RI. A clone with the Tn5 kanamycin resistance gene in the correct orientation for transcription and translation is chosen and called pCGN1537b. The 35S promoter Kan^R-tml 3' region is then transferred to a chloramphenical resistant plasmid backbone. pCGN786, (a pUC-CAM based vector with the synthetic oligonucleotide 5' GGAATTCGTCGACAGATCTCTGCAGCTCGAGGGATCCAAGCTT 3' (SEQ ID NO: 34) containing the cloning sites *Eco*RI, *Sal*I, *Bgl*II, *Pst*I, *Xho*I, *Bam*HI, and *Hin*dIII inserted into pCGN566, pCGN566 contains the *Eco*HI-*Hin*dIII linker of pUC18 inserted into the *Eco*KI-*Hin*dIII sites of pUC13-cm (K. Buckler (1985) *supra*)) is digested with *Xho*I and the *Xho*I fragment of pCGN1537b containing the 35S promoter - Kan^R-tml 3' region is ligated in. The resulting clone is termed pCGN1546.

pCGN1541b

pCGN565RBα2X (see below) is digested with *Bgl*II and *Xho*I, and the 728bp fragment containing the T-DNA right border piece and the *lac*Z' gene is ligated with *Bgl*II-*Xho*I digested pCGN65ΔKX-S+K (see below), replacing the *Bgl*II-*Xho*I right border fragment of pCGN65ΔKX-S+K. The resulting plasmid, pCGN65α2X contains both T-DNA borders and the *lac*Z' gene. The *Cla*I fragment of pCGN65α2X is

replaced with an *Xho*I site by digesting with *Cla*I blunting the ends using the Klenow fragment, and ligating with *Xho*I linker DNA, resulting in plasmid pCGN65α2XX. pCGN65α2XX is digested with *Bgl*II and *Eco*RV, treated with the Klenow fragment of DNA polymerase I to create blunt ends, and ligated in the presence of *Bgl*II linker DNA, resulting in pCGN65α2XX'. pCGN65α2XX' is digested with *Bgl*II and ligated with *Bgl*II digested pCGN1538 (see below), resulting in pCGN1541a, which contains both plasmid backbones. pCGN1541a is digested with *Xho*I and religated. Ampicillin resistant, chlormaphenicol sensitive clones are chosen, which lack the pACYC184-derived backbone, creating pCGN1541b.

pCGN1538 is generated by digesting pBR322 with *Eco*RI and *Pvu*II, treating with Klenow to generate blunt ends, and ligating with *Bgl*II linkers. pCGN1538 is ampicillin resistant, tetracycline sensitive.

pCGN65ΔKX-S+K

pCGN501 is constructed by cloning a 1.85 kb *Eco*RI-*Xho*I fragment of pTiA6 (Currier and Nester, *J. Bact.* (1976) *126*:157-165) containing bases 13362-15208 (Barker *et al.*, *Plant Mo. Biol.* (1983) *2*:335-350) of the T-DNA (right border), into *Eco*RI-*Sal*I digested M13mp9 (Vieira and Messing, *Gene* (1982) *19*:259-268). pCGN502 is constructed by cloning a 1.6 kb *Hin*dIII-*Sma*I fragment of pTiA6, containing bases 602-2212 of the T-DNA (left border), into *Hin*dIII-*Sma*I digested M13mp9. pCGN501 and pCGN502 are both digested with *Eco*RI and *Hin*dIII and both T-DNA-containing fragments cloned together into *Hin*dIII digested pUC9 (Vieira and Messing, *Gene* (1982) *19*:259-268) to yield pCGN503, containing both T-DNA border fragments. pCGN503 is digested with *Hin*dIII and *Eco*RI and the two resulting *Hin*dIII-*Eco*RI fragments (containing the T-DNA borders) are cloned into *Eco*RI digested pHC79 (Hohn and Collins, *Gene* (1980) *11*:291-298) to generate pCGN518. The 1.6kb *Kpn*I-*Eco*RI fragment from pCGN518, containing the left T-DNA border, is cloned into *Kpn*I-*Eco*RI digested pCGN565 to

generate pCGN580. The *Bam*HII-*Bgl*II fragment of pCGN580 is cloned into the *Bam*HI site of pACYC184 (Chang and Cohen, *J. Bacteriol.* (1978) *134*:1141-1156) to create pCGN51. The 1.4 kb *Bam*HI-*Sph*I fragment of pCGN60 containing the T-DNA right border fragment, is cloned into *Bam*HI-*Sph*I digested pCGN51 to create pCGN65, which contains the right and left T-DNA borders.

pCGN65 is digested with *Kpn*I and *Xba*I, treated with Klenow enzyme to create blunt ends, and ligated in the presence of synthetic *Bgl*II linker DNA to create pCGN65ΔKX. pCGN65ΔKX is digested with *Sal*I, treated with Klenow enzyme to create blunt ends, and ligated in the presence of synthetic *Xho*I linker DNA to create pCGN65ΔKX-S+X.

<u>pCGN565RBα2X</u>

pCGN451 (see below) is digested with *Hpa*I and ligated in the presence of synthetic *Sph*I linker DNA to generate pCGN55. The *Xho*I-*Sph*I fragment of pCGN55 (bp13800-15208, including the right border, of *Agrobacterium tumefaciens* T-DNA; (Barker *et al.*, *Gene* (1977) *2*:95-113) is cloned into *Sal*I-*Sph*I digested pUC19 (Yanisch-Perron *et al.*, *Gene* (1985) *53*:103-119) to create pCGN60. The 1.4 kb *Hin*dIII-*Bam*HI fragment of pCGN60 is cloned into *Hin*dIII-*Bam*HI digested pSP64 (Promega, Inc.) to generate pCGN1039. pCGN1039 is digested with *Sma*I and *Nru*I (deleting bp14273-15208; (Barker *et al.*, *Gene* (1977) *2*:95-113) and ligated in the presence of synthetic *Bgl*II linker DNA creating pCGN1039ΔNS. The 0.47 kb *Eco*RI-*Hin*dIII fragment of pCGN1039ΔNS is cloned into *Eco*RI-*Hin*dIII digested pCGN565 to create pCGN565RB. The *Hin*dIII site of pCGN565RB is replaced with an *Xho*I site by digesting with *Hin*dIII, treating with Klenow enzyme, and ligating in the presence of synthetic *Xho*I linker DNA to create pCGN565RB-H+X.

pUC18 (Norrander *et al.*, *Gene* (1983) *26*:101-106) is digested with *Hae*II to release the *lac*Z' fragment, treated with Klenow enzyme to create blunt ends, and the *lac*Z'-containing fragment ligated into pCGN565RB-H+X, which had been digested with *Acc*I and *Sph*I and treated with Klenow

enzyme in such a orientation that the *lac*Z' promoter is proximal to the right border fragment; this construct, pCGN565RBα2x is positive for *lac*Z' expression when plated on an appropriate host and contains bp 13990-14273 of the right border fragment (Barker *et al.*, *Plant Mo. Biol.* (1983) *2*:335-350) having deleted the *Acc*I-*Sph*I fragment (bp 13800-13990).

pCGN451

pCGN451 contains an ocs5'-ocs3' cassette, including the T-DNA right border, cloned into a derivative of pUC8 (Vieira and Messing, *supra*). The modified vector is derived by digesting pUC8 with *Hinc*II and ligating in the presence of synthetic linker DNA, creating pCGN416, and then deleting the *Eco*RI site of pCGN416 by *Eco*RI digestion followed by treatment with Klenow enzyme and self-ligation to create pCGN426.

The ocs5'-ocs3' cassette is created by a series of steps from DNA derived from the octopine Ti-plasmid pTiA6 (Currier and Nester, *supra*). To generate the 5'end, which includes the T-DNA right border, an *Eco*RI fragment of pTiA6 (bp 13362-16202 (the numbering is by Barker, *et al.*, *(Plant Mol. Bio* (1983) *2*:335-350) for the closely related Ti plasmid pTi15955)) is removed from pVK232 (Knauf and Nester, *Plasmid* (1982) *8*:45) by *Eco*RI digestion and cloned into *Eco*RI digested pACYC184 (Chang and Cohen, *supra*) to generate pCGN15.

The 2.4kb *Bam*HI-*Eco*RI fragment (bp 13774-16202) of pCGN15 is cloned into *Eco*RI-*Bam*HI digested pBR322 (Bolivar, *et al.*, *supra*) to yield pCGN429. The 412 bp *Eco*RI-*Bam*HI fragment (bp 13362-13772) of pCGN15 is cloned into *Eco*RI-*Bam*HI digested pBR322 to yield pCGN407. The cut-down promoter fragment is obtained by digesting pCGN407 with *Xmn*I (bp 13512), followed by resection with *Bal*31 exonuclease, ligation of synthetic *Eco*RI linkers, and digestion with *Bam*HI. Resulting fragments of approximately 130 bp are gel purified and cloned into M13mp9 (Vieira and Messing, *supra*) and sequenced. A clone, I-4, in which the *Eco*RI linker has been inserted at bp 1362 between the

transcription initiation point and the translation initiation codon is identified by comparison with the sequence of de Greve, *et al.*, (*J. Mol. Appl. Genet.* (1982) *1*:499-512). The *Eco*RI cleavage site is at position 13639, downstream from the mRNA start site. The 141 bp *Eco*RI-*Bam*HI fragment of I-4, containing the cut-down promoter, is cloned into *Eco*RI-*Bam*HI digested pBR322 to create pCGN428. The 141 bp *Eco*RI-*Bam*HI promoter piece from pCGN428, and the 2.5 kb *Eco*RI-*Bam*HI ocs5' piece from pCGN429 are cloned together into *Eco*RI digested pUC19 (Vieira and Messing, *supra*) to generate pCGN442, reconstructing the ocs upstream region with a cut-down promoter section.

To generate the ocs3' end, the *Hin*dIII fragment of pLB41 (D. Figurski, UC San Diego) containing the gentamycin resistance gene is cloned into *Hin*dIII digested pACYC184 (Chang and Cohen, *supra*) to create pCGN413b. The 4.7 kb *Bam*HI fragment of pTiA6 (*supra*), containing the ocs3' region, is cloned into *Bam*HI digested pBR325 (F. Bolivar, *Gene* (1978) *4*:121-136) to create 33c-19. The *Sma*I site at position 11207 (Barker, *supra*) of 33c-19 is converted to an *Xho*I site using a synthetic *Xho*I linker, generating pCCG401.2. The 3.8 kb *Bam*HI-*Eco*RI fragment of pCGN401.2 is cloned into *Bam*HI-*Eco*RI digested pCGN413b to create pCGN419.

The ocs5'-ocs3' cassette is generated by cloning the 2.64 kb *Eco*RI fragment of pCGN442, containing the 5' region, into *Eco*RI digested pCGN419 to create pCNG446. The 3.1kb *Xho*I fragment of pCGN446, having the ocs5' region (bp 13639-15208) and ocs3' region (bp 11207-12823), is cloned into the *Xho*I site of pCGN426 to create pCGN451.

Example 8

In this example, the preparation of a Bce-4 expression cassette containing a plant desaturase is described.

The desaturase cDNA clone from pCGN2754 prepared as described in Example 5, is modified by *in vitro* mutagenesis to insert restriction sites immediately upstream of the ATG start codon and downstream of the TGA stop codon. A

single-stranded template DNA is prepared for the mutagenesis reaction from pCGN1894 (described in Example 6) as described by Messing, (*Methods in Enzymol.* (1983) *101*:20-79). Synthetic oligonucleotides are synthesized on an Applied Biosystems 380A DNA synthesizer. The oligonucleotides used are

5'-CCATTTTTGATCTTCCTCGAGCCCGGGCTGCAGTTCTTCTTCTTCTTG-3' (SEQ ID NO: 35) for the 5'mutagenesis and

5'-GCTCGTTTTTTTTTCTCTGCAGCCCGGGCTCGAGTCACAGCTTCACC -3' (SEQ ID NO: 36) for the 3'-mutagenesis; both add *Pst*I, *Sma*I and *Xho*I sites flanking the coding region. Both oligonucleotides are 5'-phosphorylated (BRL 5'-Terminus labelling kit) and used for mutagenesis with the pCGN1894 template by the procedure of Adelman *et al.* (*DNA* (1983) *2*:183-193). Alternatively, the desired restriction sites may be inserted by PCR, using the 3' oligo described above (SEQ ID NO: 36) and another oligo, 5' ACTGACTGCAGCCCGGGCTCGAGGAAGATCAAAAATGGCTCTTC 3' (SEQ ID NO: 37) for the 3' and 5' primers, respectively. The template in this polymerase chain reaction is DNA from pCGN1894. The *Xho*I fragment from the resulting clone can be subcloned into the Bce4 expression cassette, pCGN1870 (described below) at the unique *Xho*I site. This Bce4/desaturase expression cassette can then be inserted in a suitable binary vector, transformed into *Agrobacterium tumefaciens* strain EHA101 and used to transform plants as provided in Example 10.

<u>Bce-4 Expression Cassette</u>

pCGN1870 is a Bce-4 expression cassette containing 5' and 3' regulatory regions of the Bce-4 gene and may be derived from the Bce-4 sequence found in pCGN1857, which was deposited with the ATCC on March 9, 1990, and assigned accession number 68251, or by methods known to one skilled in the art from the sequence (SEQ ID NO: 27) provided in Fig. 8. The Bce 4 gene may be isolated as follows:

The *Cla*I fragment of pCGN1857, containing the Bce4 gene is ligated into *Cla*I digested Bluescript KS+

(Stratagene; La Jolla, CA), producing pCGN1864. Single stranded DNA is made from pCGN1864 and altered by *in vitro* mutagenesis using the oligonucleotides

BCE45P:

(5'GAGTAGTGAACTTCATGGATCCTCGAGGTCTTGAAAACCTAGA3') (SEQ ID NO: 38) and

BCE43P:

(5'CAATGTCTTGAGAGATCCCGGGATCCTTAACAACTAGGAAAAGG3') (SEQ ID NO: 39)

as described by Adelman *et al.* (*DNA* (1983) *2*:183-193). The oligonucleotide BSCP2 (5'GTAAGACACGACTTATCGCCACTG3') (SEQ ID NO: 40), complementary to a portion of Bluescript, is included in the reaction to improve the yield of double-stranded DNA molecules. The resulting plasmid, pCGN1866, contains *Xho*I and *Bam*HI sites (from BCE45P) immediately 5' to the Bce4 start codon and *Bam*HI and *Sma*I sites (from BCE43P) immediately 3' to the Bce4 stop codon. The *Cla*I fragment of pCGN1866, containing the mutagenized sequences, is inserted into the *Cla*I site of pCGN2016 (described in Example 6), producing pCGN1866C. The *Cla*I fragment of pCGN1866C is used to replace the corresponding wild-type *Cla*I fragment of PCGN1867 (described below) to produce pCGN1868. Bce4 coding sequences are removed by digestion of pCGN1868 with *Bam*HI and recircularization of the plasmid to produce pCGN1870. The Bce4 expression cassette, pCGN1870, contains 7.4 kb of 5' regulatory sequence and 1.9 kb of 3' regulatory sequence derived from the Bce4 genomic clone separated by the cloning sites, *Xho*I, *Bam*HI, and *Sma*I. Desaturase sequences in sense or anti-sense orientation may be inserted into the cassette via the cloning sites and the resulting construct may be employed in a plant transformation technique.

pCGN1867

The *Bam*HI and *Sma*I sites of pUC18 are removed by *Bam*HI-*Sma*I digestion and recircularizing of the plasmid, without repair of the ends, to produce pCGN1862 The *Pst*I fragment of pCGN1857, containing the Bce4 gene, is inserted into the *Pst*I site of pCGN1862 to produce pCGN1867.

Example 9

In this example, the preparation of a napin 1-2 expression cassette containing a plant desaturase is described.

Preparation of Desaturase Clone

The desaturase cDNA clone from pCGN2754 is prepared and modified as described in Example 8. The *Xho*I fragment from the resulting clone can be subcloned into the napin 1-2 expression cassette, pCGN1808 (described below) at the unique *Xho*I site. This napin 1-2/desaturase expression cassette can then be inserted into a suitable binary vector, transformed into *A. tumefaciens* strain EHA101 in a like manner as described in Example 7.

Alternatively, the desaturase safflower clone may be prepared such that restriction sites flank the translation start and stop sites, as described in Example 8, with the following modification. PCR was carried out according to manufacturer's instructions except for the initial annealing of the oligonucleotides to the template. The reaction mix was heated to 90°C for 5 min, cooled to 37°C over a one hour period, kept at 37°C for 20 min and then subjected to standard PCR cycles. The PCR product was digested with *Pst*I and ligated to pUC8 (Vieira and Messing (1982) *Gene 19*:2359-268) digested with *Pst*I to produce pCGN3220. The *Nco*I/*Sac*I fragment of pCGN3220 containing the pUC8 vector and the 5' and 3' sequences of the safflower desaturase cDNA was gel purified and ligated to the gel-purified cloned *Nco*I/*Sac*I fragment from pCGN1894 (see Example 6). The resulting plasmid pCGN3222 contains safflower desaturase cDNA sequences partially from the cDNA

clone and partially from the PCR. The regions obtained from the PCR were confirmed by DNA sequencing as being identical to the original cloned sequence.

Expression Cassettes

Napin 1-2 pCGN1808 Expression Cassette

An expression cassette utilizing 5' upstream sequences and 3' downstream sequences obtainable from *B. campestris* napin gene can be constructed as follows.

A 2.7 kb *Xho*I fragment of napin 1-2 (Fig. 10 and SEQ ID NO: 29) containing 5' upstream sequences is subcloned into pCGN789 (a pUC based vector the same as pUC119 with the normal polylinker replaced by the synthetic linker - 5'GGAATTCGTCGACAGATCTCTGCAGCTCGAGGGATCCAAGCTT 3', SEQ ID NO: 41, (which represented the polylinker *Eco*RI, *Sal*I, *Bgl*II, *Pst*I, *Xho*I, *Bam*HI, *Hin*dIII) and results in pCGN940. The majority of the napin coding region of pCGN940 was deleted by digestion with *Sal*I and religation to form pCGN1800. Single-stranded DNA from pCGN1800 was used in an *in vitro* mutagenesis reaction (Adelman *et al.*, *DNA* (1983) *2*:183-193) using the synthetic oligonucleotide 5' GCTTGTTCGCCATGGATATCTTCTGTATGTTC 3', SEQ ID NO: 42. This oligonucleotide inserted an *Eco*RV and an *Nco*I restriction site at the junction of the promoter region and the ATG start codon of the napin gene. An appropriate mutant was identified by hybridization to the oligonucleotide used for the mutagenesis and sequence analysis and named pCGN1801.

A 1.7 kb promoter fragment was subcloned from pCGN1801 by partial digestion with *Eco*RV and ligation to pCGN786 (a pCGN566 chloramphenicol based vector with the synthetic linker described above in place of the normal polylinker) cut with *Eco*RI and blunted by filling in with DNA Polymerase I Klenow fragment to create pCGN1802.

A 2.1 kb *Sal*I fragment of napin 1-2 (Fig. 10 and SEQ ID NO: 29) containing 3' downstream sequences is subcloned into pCGN789 (described above) and results in pCGN941. pCGN941 is digested with *Xho*I and *Hin*dIII and the resulting approximately 1.6 kb of napin 3' sequences are inserted

into *Xho*I-*Hin*dIII digested pCGN1802 to result in pCGN1803. In order to remove a 326 nucleotide *Hin*dIII fragment inserted opposite to its natural orientation, as a result of the fact that there are 2 *Hin*dIII sites in pCGN1803, the pCGN1803 is digested with *Hin*dIII and religated. Following religation, a clone is selected which now contains only 1.25 kb of the original 1.6 napin 3' sequence. This clone, pCGN1808 is the napin 1-2 expression cassette and contains 1.725 kb of napin promoter sequences and 1.265 kb of napin 3' sequence with the unique cloning sites *Sal*I, *Bgl*I, *Pst*I and *Xho*I in between.

Napin 1-2 pCGN3223 Expression Cassette

Alternatively, pCGN1808 may be modified to contain flanking restriction sites to allow movement of only the expression sequences and not the antibiotic resistance marker to binary vectors such as pCGN1557 (McBride and Summerfelt, *supra*). Synthetic oligonucleotides containing *Kpn*I, *Not*I and *Hin*dIII restriction sites are annealed and ligated at the unique *Hin*dIII site of pCGN1808, such that only one *Hin*dIII site is recovered. The resulting plasmid, pCGN3200 contains unique *Hin*dIII, *Not*I and *Kpn*I restriction sites at the 3'-end of the napin 3'-regulatory sequences as confirmed by sequence analysis.

The majority of the napin expression cassette is subcloned from pCGN3200 by digestion with *Hin*dIII and *Sac*I and ligation to *Hin*dIII and *Sac*I digested pIC19R (Marsh, *et al.* (1984) *Gene 32*:481-485) to make pCGN3212. The extreme 5'-sequences of the napin promoter region are reconstructed by PCR using pCGN3200 as a template and two primers flanking the *Sac*I site and the junction of the napin 5'-promoter and the pUC backbone of pCGN3200 from the pCGN1808 construct. The forward primer contains *Cla*I, *Hin*dIII, *Not*I, and *Kpn*I restiction sites as well as nucleotides 408-423 of the napin 5'-sequence (from the *Eco*RV site) and the reverse primer contains the complement to napin sequences 718-739 which include the unique *Sac*I site in the 5'-promoter. The PCR was performed using a Perkin Elmer/Cetus

thermocycler according to manufacturer's specifications. The PCR fragment is subclon d as a blunt-ended fragment into pUC8 (Vieira and M ssing (1982) *Gene 19*:259-268) and digested with *Hinc*II to give pCGN3217. Sequence of pCGN3217 across the napin insert verifies that no improper nucleotides were introduced by PCR. The napin 5-sequences in pCGN3217 are ligated to the remainder of the napin expression cassette by digestion with *Cla*I and *Sac*I and ligation to pCGN3212 digested with *Cla*I and *Sac*I. The resulting expression cassette pCGN3221, is digested with *Hin*dIII and the napin expression sequences are gel purified away and ligated to pIC20H (Marsh, *supra*) digested with *Hin*dIII. The final expression cassette is pCGN3223, which contains in an ampicillin resistant background, essentially identical 1.725 napin 5' and 1.265 3' regulatory sequences as found in pCGN1808. The regulatory regions are flanked with *Hin*dIII, *Not*I and *Kpn*I restriction sites and unique *Sal*I, *Bgl*II, *Pst*I, and *Xho*I cloning sites are located between the 5' and 3' noncoding regions.

Desaturase sequences in sense or anti-sense orientation may be inserted into a napin expression cassette via the cloning sites. The resulting construct may be employed for plant transformation. For example, one of ordinary skill in the art could also use known techniques of gene cloning, mutations, insertion and repair to allow cloning of a napin expression cassette into any suitable binary vector, such as pCGN1557 (described in Example 7) or other similar vectors.

Desaturase Expression

The coding region of the safflower desaturase contained in pCGN3222 is cloned into the pCGN3223 napin cassette by digestion with *Xho*I and ligation to pCGN3223 digested with *Xho*I and *Sal*I. The resulting plasmid, pCGN3229 is digested with *Asp*718 and inserted in the binary vector pCGN1578 (McBride and Summerfelt (1990) *Plant Mol. Biol. 14*:269-276) at the unique *Asp*718 site. The resulting binary vector is pCGN3231 and contains the safflower

desaturase coding sequences flanked by the napin 5' and 3' regulatory s quences as well as the plant selectable marker construct, 35s/NPTII/tml.

The resulting binary vector, pCGN3231, is transformed into *Agrobacterium* and utilized for plant transformation as described in Example 10. For Northern analysis, total RNA is isolated from day 21 and day 28 post-anthesis developing seed from plants transformed with pCGN3231. Five samples were analyzed at day 21 and two at day 28 post-anthesis. RNA was isolated by the method of Hughes and Galau (*Plant Mol. Biol. Reporter* (1988) *6*: 253-257). Northern blot analysis was performed using a labeled 0.8 kb *Bgl*II fragment of pCGN1894 as a probe. Prehybridization and hybridization was at 42°C in 50% formamide, 10X Denhardt's solution, 5X SSC, 0.1% SDS, 5mM EDTA and 100ug/ml denatured salmon sperm DNA. Filters were washed at 55°C in 0.1 X SSC, 0.1% SDS. Under these conditions, the probe does not hybridize to the endogenous *Brassica* desaturase gene sequences. mRNA complementary to the safflower desaturase was detected in all the transgenic samples examined. More mRNA was present at day 28 than at day 21 post-anthesis and the highest level of RNA was seen in transgenic 3231-8. The total safflower desaturase mRNA level was estimated to be ~0.01% of the message at day 28 post-anthesis.

Western analysis (see below) gives a preliminary indication of increased protein in one transformant, 3231-8. However, the Western analysis is complicated by two factors: 1. The presence of cross-reacting material at the same molecular weight as expected for the safflower desaturase. We believe this material is the endogenous *Brassica* desaturase. 2. The analysis of levels of protein expressed is also complicated by the normal developmental increase in the expression of desaturase protein during this time period. If the seeds examined are not at the precise developmental stage as the control seeds, quantitative differences in the amount of material seen may be simply due to the normal increase in the *Brassica*

desaturase over this time period and not due to the expression of the safflower desaturase.

Western Analysis

Soluble protein is extracted from developing seeds of *Brassica* by homogenization with one volume (1ml/gram fresh weight) of buffer containing 20mM potassium phosphate, pH 6.8. The homogenate is clarified by centrifugation at 12,000 x *g* for 10 minutes. A second centrifugation is performed if necessary to provide a non-particulate supernatant.

Protein concentration of the extract is measured by the micromethod of Bradford (*Anal. Biochem.* (1976) *72*:248-254). Proteins (20-60μg) are separated by denaturing electrophoresis by the method of Laemmli (*supra*), and are transferred to nitrocellulose membrane by the method of Towbin *et al.* (*Proc. Nat. Acad Sci.* (1979) *76*:4350-4354).

The nitrocellulose membrane is blocked by incubation at room temperature for 15 minutes or at 4°C overnight in Tris-buffered saline with Tween 20 (Polyoxyethylenesorbitan monolaurate) and "TTBS-milk", (TTBS = 20mM Tris-HCl, 500mM NaCl, 0.1% Tween 20 (v/v), pH 7.5; "TTBS-milk" = TTBS and 3% skim milk powder). The volume of liquid in all incubations with the nitrocellulose membrane is sufficient to cover the membrane completely. The membrane is then incubated for an additional 5 minutes in TTBS.

The nitrocellulose membrane is incubated for at least one hour with shaking at room temperature with rabbit anti-stearoyl-ACP desaturase antiserum that was diluted 5,000- or 10,000-fold in "TTBS-milk". The rabbit anti-desaturase antiserum was commercially prepared from desaturase protein (purified as described in Example 1) by Berkeley Antibody Co. (Richmond, CA). The membrane is washed twice by shaking with TTBS for 5 minutes and then with deionized H_2O for 30 seconds.

The nitrocellulose membrane is incubated for at least 45 minutes at room temperature in a solution of "TTBS-milk" in which anti-rabbit IgG-alkaline phosphatase conjugate

(Promega, Madison, WI) is diluted 7,500-fold. Th membrane is washed twice in TTBS followed by deionized H_2O, as described above.

The nitrocellulose membrane is equilibrated in buffer containing 100mM Tris-HCl, 100mM NaCl, 50mM $MgCl_2$, pH 9.5, by shaking for 5 minutes. The color reaction is initiated by placing the nitrocellulose membrane into 50ml of the same buffer to which has been added 15mg *p*-nitroblue tetrazolium chloride and 7.5mg 5-bromo- 4 chloro- 3-indolyl phosphate toluidine salt (BioRad Labs; Richmond, CA). The color reaction is stopped by rinsing the nitrocellulose membrane with deionized H_2O and drying it between filter papers.

Oil analysis of developing seeds indicated no significant change in oil composition of the transformed plants with respect to the control plants. This result is consistant with the low levels of safflower mRNA observed in transgenic plants as compared to levels of endogenous *Brassica* desaturase (Example 12).

Example 10

In this example, an *Agrobacterium*-mediated plant transformation is described. *Brassica napus* is exemplified. The method is also useful for transformation of other *Brassica* species including *Brassica campestris*.

Plant Material and Transformation

Seeds of *Brassica napus* cv. Delta are soaked in 95% ethanol for 2 min, surface sterilized in a 1.0% solution of sodium hypochlorite containing a drop of Tween 20 for 45 min., and rinsed three times in sterile, distilled water. Seeds are then plated in Magenta boxes with 1/10th concentration of Murashige minimal organics medium (Gibco) supplemented with pyrodoxine (50 µg/l), nicotinic acid (50 µg/l), glycine (200 µg/l), and 0.6% Phytagar (Gibco) pH 5.8. Seeds are germinated in a culture room at 22°C in a 16 h photoperiod with cool fluorescent and red light of

intensity approximately 65 µEinsteins per square meter per second ($\mu Em^{-2}S^{-1}$).

Hypocotyls are excised from 7 day old seedlings, cut into pieces approximately 4 mm in length, and plated on feeder plates (Horsch et al. 1985). Feeder plates are prepared one day before use by plating 1.0 ml of a tobacco suspension culture onto a petri plate (100x25 mm) containing about 30 ml MS salt base (Carolina Biological) 100 mg/l inositol, 1.3 mg/l thiamine-HCl, 200 mg KH_2PO_4 with 3% sucrose, 2,4-D (1.0 mg/l), 0.6% Phytagar, and pH adjusted to 5.8 prior to autoclaving (MS0/1/0 medium). A sterile filter paper disc (Whatman 3 mm) is placed on top of the feeder layer prior to use. Tobacco suspension cultures are subcultured weekly by transfer of 10 ml of culture into 100 ml fresh MS medium as described for the feeder plates with 2,4-D (0.2 mg/l), Kinetin (0.1 mg/l). All hypocotyl explants are preincubated on feeder plates for 24 h. at 22°C in continuous light of intensity 30 $\mu Em^{-2}S^{-1}$ to 65 $\mu EM^{-2}S^{-1}$.

Single colonies of *A. tumefaciens* strain EHA101 containing a binary plasmid are transferred to 5 ml MG/L broth and grown overnight at 30°C. Per liter, MG/L broth contains 5g mannitol, 1 g L-glutamic acid or 1.15 g sodium glutamate, 0.25 g kH_2PO_4, 0.10 g NaCL, 0.10 g $MGSO_4 \cdot 7H_2O$, 1 mg biotin, 5 g tryptone, and 2.5 g yeast extract, and the broth is adjusted to pH 7.0. Hypocotyl explants are immersed in 7-12 ml MG/L broth with bacteria diluted to $1x10^8$ bacteria/ml and after 10-20 min. are placed onto feeder plates. After 48 h of co-incubation with *Agrobacterium*, the hypocotyl explants are transferred to B5 0/1/0 callus induction medium which contains filter sterilized carbenicillin (500 mg/l, added after autoclaving) and kanamycin sulfate (Boehringer Mannheim) at concentrations of 25 mg/l.

After 3-7 days in culture at 65 $\mu Em^{-2}S^{-1}$ to 75 $\mu Em^{-2}S^{-1}$ continuous light, callus tissue is visible on the cut surface and the hypocotyl explants are transferred to shoot induction medium, B5BZ (B5 salts and vitamins supplemented

with 3 mg/l benzylaminopurine, 1 mg/l zeatin, 1% sucrose, 0.6% Phytagar and pH adjusted to 5.8). This medium also contains carbenicillin (500 mg/l) and kanamycin sulfate (25 mg/l). Hypocotyl explants are subcultured onto fresh shoot induction medium every two weeks.

Shoots regenerate from the hypocotyl calli after one to three months. Green shoots at least 1 cm tall are excised from the calli and placed on medium containing B5 salts and vitamins, 1% sucrose, carbenicillin (300 mg/l), kanamycin sulfate (50 mg/l) and 0.6% Phytagar) and placed in a culture room with conditions as described for seed germination. After 2-4 weeks shoots which remain green are cut at the base and transferred to Magenta boxes containing root induction medium (B5 salts and vitamins, 1% sucrose, 2 mg/l indolebutyric acid, 50 mg/l kanamycin sulfate and 0.6% Phytagar). Green rooted shoots are tested for NPT II activity.

Example 11

In this example, a DNA-bombardment plant transformation is described. Peanut transformation is exemplified.

DNA sequences of interest may be introduced as expression cassettes, comprising at least a promoter region, a gene of interest, and a termination region, into a plant genome via particle bombardment as described in European Patent Application 332 855 and in co-pending application USSN 07/225,332, filed July 27, 1988.

Briefly, tungsten or gold particles of a size ranging from 0.5µM-3µM are coated with DNA of an expression cassette. This DNA may be in the form of an aqueous mixture or a dry DNA/particle precipitate.

Tissue used as the target for bombardment may be from cotyledonary explants, shoot meristems, immature leaflets, or anthers.

The bombardment of the tissue with the DNA-coated particles is carried out using a Biolistics™ particle gun (Dupont; Wilmington, DE). The particles are placed in the barrel at variable distances ranging from 1cm-14cm from the

barrel mouth. The tissue to be bombarded is placed beneath the stopping plate; testing is performed on the tissue at distances up to 20 cm. At the moment of discharge, the tissue is protected by a nylon net or a combination of nylon nets with mesh ranging from 10μM to 300μM.

Following bombardment, plants may be regenerated following the method of Atreya, *et al.*, (*Plant Science Letters* (1984) *34*:379-383). Briefly, embryo axis tissue or cotyledon segments are placed on MS medium (Murashige and Skoog, *Physio. Plant.* (1962) *15*:473) (MS plus 2.0 mg.1 6-benzyladenine (BA) for the cotyledon segments) and incubated in the dark for 1 week at 25 ± 2°C and are subsequently transferred to continuous cool white fluorescent light (6.8 W/m^2). On the 10th day of culture, the plantlets are transferred to pots containing sterile soil, are kept in the shade for 3-5 days are and finally moved to greenhouse.

The putative transgenic shoots are rooted. Integration of exogenous DNA into the plant genome may be confirmed by various methods known to those skilled in the art.

Example 12

This example describes methods to obtain desaturase cDNA clones from other plant species using the DNA from the *C. tinctorius* Δ-9 desaturase clone as the probe.

Isolation of RNA for Northern Analysis

Poly(A)+ RNA is isolated from *C. tinctorius* embryos collected at 14-17 days post-anthesis and *Simmondsia chinensis* embryos as described in Example 5.

Total RNA is isolated from days 17-18 days post-anthesis *Brassica campestris* embryos by an RNA minipreparation technique (Scherer and Knauf, *Plant Mol. Biol.* (1987) *9*:127-134). Total RNA is isolated from *R. communis* immature endosperm of about 14-21 days post-anthesis by a method described by Halling, *et al.* (*Nucl. Acids Res.* (1985) *13*:8019-8033). Total RNA is isolated

from 10 g each of young leaves from *B. campestris*, *B. napus*, and *C. tinctorius*, by extraction of each sample in 5 ml/g tissue of 4 M guanidine thiocyanate buffer as described by Colbert *et al.* (*Proc. Nat. Acac. Sci.* (1983) *80*:2248-2252). Total RNA is also isolated from immature embryos of *Cuphea hookeriana* by extraction as above in 10 ml/g tissue.

Total RNA is isolated from immature embryos of California bay (*Umbellularia californica*) by an adaptation of the method of Lagrimini *et al.* (*Proc. Nat. Acad. Sci.* (1987) *84*:7542-7546). Following homogenization in grinding buffer (2.5 ml/g tissue) as described, RNA is precipitated from the aqueous phase by addition of 1/10 volume 3 M sodium acetate and 2 volumes ethanol, followed by freezing at -80°C for 30 minutes and centrifugation at 13,000 x g for 20 minutes. The pellets are washed with 80% ethanol and centrifugation is repeated as above. The pellets are resuspended in water, two volumes of 4 M LiCl are added, and the samples are placed at -20°C overnight. Samples are centrifuged as above and the pellets washed with 80% ethanol. Ethanol precipitation is repeated as above.

Total RNA is further purified from *B. campestris*, *B. napus*, and *C. tinctorius* leaves, and from *C. tinctorius*, *B. campestris*, California bay, and jojoba, and from *R. communis* immature endosperm, by removing polysaccharides on a 0.25 g Sigma Cell 50 cellulose column. The RNA is loaded onto the column in 1 ml of loading buffer (20 mM Tris-HCl pH 7.5, 0.5M NaCl, 1mM EDTA, 0.1% SDS), eluted with loading buffer, and collected in 500 µl fractions. Ethanol is added to the samples to precipitate the RNA. The samples are centrifuged, and the pellets resuspended in sterile distilled water, pooled, and again precipitated in ethanol. The sample is centrifuged, and the resulting RNA is subjected to oligo(dT)-cellulose chromatography to enrich for poly(A)+ RNA as described by Maniatis *et al.* (*Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory, New York (1982)). Poly(A)+ RNA is also

purified from total *Cuphea hookeriana* RNA by oligo(dT)-cellulose chromatography.

Northern Analysis Using C. tinctorius Desaturase Clone: 2.5 µg of poly(A)+ RNA from each of the above described poly(A)+ samples from immature embryos of jojoba, *Cuphea hookeriana*, California bay, *Brassica campestris*, and *C. tinctorius*, from immature endosperm of *R. communis*, and from leaves of *C. tinctorius*, *B. campestris*, and *B. napus* are electrophoresed on formaldehyde/agarose gels (Fourney *et al.*, *Focus* (1988) *10*:5-7) and transferred to a Hybond-C extra (Amersham, Arlington Heights, IL) filter according to manufacturer's specifications. The filter is prehybridized for four hours and hybridized overnight at 42°C in a roller bottle containing 10 ml of hybridization buffer (1 M NaCl, 1% SDS, 50% formamide, 0.1 mg/ml denatured salmon sperm DNA) in a Hybridization Incubator, model 1040-00-1 (Robbins Scientific Corporation, Sunnyvale, CA). The probe used in the hybridization is a gel-isolated *Bgl*II fragment of the Δ-9 desaturase clone that is labeled with ^{32}P-dCTP using a BRL (Gaithersburg, MD) nick-translation kit, following manufacturer's instructions. The blot is washed three times for 20 minutes each in 2X SSC, 0.5% SDS at 55°C. The blot is exposed at -80°C, with a Dupont Cronex intensifying screen, to X-ray film for four days.

The autoradiograph shows that the *C. tinctorius* desaturase gene is expressed in both immature embryos and leaves of *C. tinctorius*, although the level of expression is considerably higher in embryos than in leaves. The autoradiograph also shows hybridization of the *C. tinctorius* desaturase clone to mRNA bands of a similar size in immature embryos from jojoba and California bay, and immature endosperm from *R. communis*. Hybridization is also detectable in RNA from *B. campestris* embryos upon longer exposure of the filter to X-ray film.

R. communis cDNA Library Construction: A plant seed cDNA library may be constructed from poly(A)+ RNA isolated from *R. communis* immature endosperm as described above. The plasmid cloning vector pCGN1703, and cloning method are

as described in Example 5. The *R. communis* endosperm cDNA bank contains approximately 2x10^6 clones with an average cDNA insert size of approximately 1000 base pairs.

The *R. communis* immature endosperm cDNA bank is moved into the cloning vector lambda gt22 (Stratagene Cloning Systems) by digestion of total cDNA with *Not*I and ligation to lambda gt22 DNA digested with *Not*I. The resulting phage are packaged using a commercially available kit and titered using *E. coli* strain LE392 (Stratagene Cloning Systems, La Jolla, CA). The titer of the resulting library was approximately 1.5 x 10^7 pfu/ml.

R. communis cDNA Library Screen: The library is plated on *E. coli* strain LE392 at a density of approximately 25,000 pfu/150mm NZY plate to provide approximately 50,000 plaques for screening. Phage are lifted in duplicate on to NEN (Boston, MA.) Colony/Plaque Screen filters as described in Example 5. Following prehybridization at 42°C in 25 ml of hybridization buffer (1 M NaCl, 1% SDS, 50% formamide, 0.1 mg/ml denatured salmon sperm DNA) filters are hybridized overnight with a gel-purified 520 base pair *Bgl*II fragment of the *C. tinctorius* desaturase clone (Figure 7A) that is radiolabeled with ^{32}P-dCTP using a BRL (Gaithersburg, MD) Nick Translation System. Filters are washed three times for 20 minutes each in 2X SSC, 0.5% SDS at 55°C in a shaking water bath. Filters are exposed to X-ray film overnight at -80°C with a Dupont Cronex intensifying screen.

Clones are detected by hybridization on duplicate filters with the *C. tinctorius* desaturase cDNA fragment and plaque purified. During plaque purification, it was observed that larger plaques were obtained when *E. coli* strain Y1090 (Young, R.A. and Davis, R.W., *Proc. Natl. Acad. Sci. USA* (1983) *80*:1194) was used as the host strain. This strain was thus used in subsequent plaque purification steps. Phage DNA is prepared from the purified clones as described by Grossberger (*NAR* (1987) *15*:6737) with the following modification. The proteinase K

treatment is replaced by the addition of 10% SDS and a 10 minute incubation at room temperature. Recovered phage DNA is digested with *Eco*RI, religated at low concentration, and transformed into *E. coli* DH5α(BRL; Gaithersburg, MD) cells to recover plasmids containing cDNA inserts in pCGN1703. Minipreparation DNA (Maniatis *et al., supra*) is prepared from the clones and DNA sequence is determined as described above. Partial nucleotide sequence of the cDNA insert of a *R. communis* desaturase clone pCGN3230 is presented in Figure 3A and SEQ ID NO: 14. The complete nucleotide sequence of this clone is presented in Fig. 3B and as SEQ ID NO: 15.

Northern Analysis Using R. communis Desaturase Clone: Total RNA for Northern analysis is isolated from tobacco leaves by the method of Ursin *et al.*(*Plant Cell* (1989) *1*:727-736), petunia and tomato leaves by the method of Ecker and Davis (*Proc.Nat.Acad.Sci.* (1987) *84*:5202-5206), and corn leaves by the method of Turpen and Griffith (*Biotechniques* (1986) *4*:11-15). Total RNA samples from tobacco, corn, and tomato leaves are enriched for poly(A)+ RNA by oligo(dT)-cellulose chromatography as described by Maniatis *et al.* (*supra*).

Poly(A)+ RNA samples from tomato leaves (4 μg) and corn and tobacco leaves (1 μg each), and total RNA from petunia leaves (25 μg) are electrophoresed on a formaldehyde/agarose gel as described by Shewmaker *et al.* (*Virology* (1985) *140*:281-288). Also electrophoresed on this gel are poly(A)+ RNA samples isolated from *B. campestris* day 17-19 embryos and *B. campestris* leaves (2 μg each), immature embryos from *C. tinctorius*, bay, and jojoba (1 μg each), and *R. communis* endosperm (1 μg). The isolation of these poly(A)+ RNA samples is described above for the Northern analysis using *C. tinctorius* desaturase cDNA as probe. The RNA is transferred to a nitrocellulose filter as described by Shewmaker *et al.* (*supra*) and prehybridized and hybridized at 42°C in 50% formamide, 10X Denhardt's solution (described in Maniatis *et al.* (supra)), 5X SSC, 0.1% SDS, 5 mM EDTA, 100 ug/ml denatured salmon

sperm DNA, and 10% dextran sulfate (in hybridization buffer only). The probe for hybridization is the ^{32}P-labeled (BRL Nick Translation Kit) 1.7 kb SalI insert of pCGN3230 that has been gel-purified from minipreparation DNA. The filter is washed following hybridization for 30 minutes in 2X SSC, 0.1% SDS at 42°C and at 50°C twice for 15 minutes each. The filter is exposed to X-ray film overnight at -80°C with a Dupont Cronex intensifying screen.

The autoradiograph shows hybridization of the *R. communis* desaturase clone to mRNA bands of a similar size in immature embryos from *B. campestris*, California bay, and *C. tinctorius*, and also in corn leaves and *R. communis* endosperm.

B. campestris Embryo cDNA Library Construction: Total RNA is isolated from 5 g of *B. campestris* cv. R500 embryos obtained from seeds harvested at days 17-19 post-anthesis. RNA is extracted in 25 mls of 4 M guanidine thiocyanate buffer as described by Colbert *et al.*(*PNAS* (1983) *80*:2248-2252). Polysaccharides are removed from the RNA sample by resuspending the pellet in 6 ml of 1X TE (10 mM Tris/1 mM EDTA pH 8), adding potassium acetate to a concentration of 0.05M, and adding one half volume of ethanol. The sample is placed on ice for 60 minutes and centrifuged for 10 minutes at 3000 x g. RNA is precipitated from the supernatant by adding sodium acetate to a concentration of 0.3 M followed by the addition of two volumes of ethanol. RNA is recovered from the sample by centrifugation at 12,000 x g for 10 minutes and yield calculated by UV spectrophotometry. Two mg of the total RNA is further purified by removing polysaccharides on a 0.25 g Sigma Cell 50 cellulose column, as described above, and is also enriched for poly(A)+ RNA by oligo(dT)-cellulose chromatography as described above.

A *B. campestris* day 17-19 post anthesis embryo cDNA library is constructed in plasmid vector pCGN1703 as described in Example 5, using 5 ug of the above described poly(A)+ RNA. The library, which consists of approximately 1.5 x 10^5 transformants, is amplified by plating and scraping colonies, and is stored as frozen *E. coli* cells in

10% DMSO at -80° C. DNA is isolated from a portion of the amplified library by scaling up the alkaline lysis technique of Birnboim and Doly (*Nucleic Acids Res.* (1979) 7:1513), and purified by CsCl centrifugation. Library DNA is digested with *Eco*RI and is cloned into *Eco*RI-digested bacteriophage lambda gt10 (Stratagene; La Jolla, CA) DNA. The DNA is packaged using Gigapack II Gold *in vitro* packaging extracts (Stratagene; La Jolla, CA) according to manufacturer's specifications. The titer of the phage stock, determined by dilution plating of phage in *E. coli* C600 hfl- cells (Huynh, *et al., DNA Cloning. Volume 1.* Eds. Gover, D.M. (1985) IRL Press Limited: Oxford, England, pp. 56,110), is 6 x 10^6 pfu per ml.

B. campestris cDNA Library Screen: The library is plated on *E. coli* strain C600 hfl- at a density of approximately 30,000 pfu/150mm NZY plate to provide approximately 120,000 plaques for screening. Phage are lifted in duplicate on to NEN (Boston, MA.) Colony/Plaque Screen filters as described in Example 5. Filters are prehybridized and hybridized with the ^{32}P-labeled fragment of pCGN3230 as described above for the Northern hybridization. Filters are washed for 30 minutes in 2X SSC, 0.1% SDS at 50°C and at 55°C twice for 15 minutes each. Filters are exposed to X-ray film overnight at -80°C with a Dupont Cronex intensifying screen.

Clones are detected by hybridization on duplicate filters to the *R. communis* desaturase cDNA fragment and plaque purified. During plaque purification, the probe used was a gel-purified 1.4 kb SstI fragment of pCGN3230 which lacks the poly(A)+ tail. As described above, phage DNA is isolated from purified lambda clones, digested with EcoRI, ligated, and transformed to *E. coli* DH5α cells. Minipreparation DNA is prepared and partial DNA sequence determined as described above. Partial DNA sequences of two clones, pCGN3235 and pCGN3236, are presented in Figure 4A (SEQ ID NO: 17) and 4B (SEQ ID NO: 18), respectively. Initial DNA sequence analysis of the 3' regions of these clones indicates that pCGN3236 and pCGN3235 are cDNA

clones from the same gene. pCGN3236 is a shorter clon than pCGN3235, which appears to contain the entire coding region of the *B. campestris* desaturase gene. The complete nucleotide sequence of pCGN3235 is presented in Figure 4C and SEQ ID NO: 19.

Desaturase Gene Analysis: Southern and Northern analyses of Brassica species are conducted to determine the number of genes which encode the Brassica desaturase clone, pCGN3235 in *B. campestris*, *B. oleracea*, and *B. napus*, and the timing of expression of the gene in *B. campestris* developing seeds. DNA is isolated from leaves of each of the above-named *Brassica* species by the method of Bernatzky and Tanksley (*Theor. Appl. Genet.* (1986) *72*:314-321). DNA from each of the species is digested with restriction endonucleases EcoRI and XbaI (10 ug/digest), electrophoresed in a 0.7% agarose gel, and transferred to a nitrocellulose filter (Maniatis *et al.*, *supra*). The filter is prehybridized and hybridized at 42°C (as described above for Northern analysis using *R. communis* desaturase clone) with a ^{32}P-labeled (nick translation) gel-isolated HindIII/PvuII fragment of pCGN3235 (Fig. 7C). The filter is washed following overnight hybridization, for 30 minutes at 55°C in 1X SSC, 0.1% SDS, followed by two 15 minute washed at 55°C in 0.1X SSC, 0.1% SDS.

The autoradiograph indicates that the *Brassica* desaturase is encoded by a small gene family consisting of about two genes in *B. campestris* and *B. oleracea*, and about four genes in *B. napus*.

The timing of expression of the desaturase gene during seed development is determined by Northern analysis. RNA is isolated from immature seeds of *B. campestris* cv. R500 collected at 11, 13, 15, 17, 19, 21, 25, 30, 35, and 40 days post-anthesis. Total RNA is isolated as described by Scherer and Knauf (*Plant Mol. Biol.* (1987) *9*:127-134). Twenty five micrograms of RNA from each time point are electrophoresed through a formaldehyde-containing 1.5% agarose gel as described by Shewmaker, *et al.* (*supra*) and blotted to nitrocellulose (Thomas, *Proc. Nat. Acad. Sci.*

(1980) *77*:5201-5205). The blot is pre-hybridized and hybridized at 42°C with the ^{32}P-labeled HindIII/PvuII fragment of pCGN3235 as described above. The filter is washed following overnight hybridization, for 30 minutes at 55°C in 1X SSC, 0.1% SDS, followed by two 15 minute washed at 55°C in 0.1X SSC, 0.1% SDS.

The autoradiograph indicates that the desaturase gene is expressed in *B. campestris* developing seeds beginning at about day 19 and through about day 30, with maximal expression at day 25. By a similar Northern analysis, the level of desaturase mRNA in developing *Brassica napus* seeds (day 21) was estimated to be approximately 1% of the total mRNA.

Isolation of Other Desaturase Gene Sequences: cDNA libraries may be constructed as described above and genomic libraries can be constructed from DNA from various sources using commercially available vectors and published DNA isolation, fractionation, and cloning procedures. For example, a *B. campestris* genomic library can be constructed using DNA isolated according to Scofield and Crouch (J.Biol.Chem. (1987) 262:12202-12208) that is digested with BamHI and fractionated on sucrose gradients (Maniatis *et al., supra*), and cloned into the lambda phage vector LambdaGem-11 (Promega; Madison,WI) using cloning procedures of Maniatis *et al.* (*supra*).

cDNA and genomic libraries can be screened for desaturase cDNA and genomic clones, respectively, using published hybridization techniques. Screening techniques are described above for screening libraries with DNA fragments. Libraries may also be screened with synthetic oligonucleotides, for example using methods described by Berent *et al.* (*BioTechniques* (1985) *3*:208-220). Probes for the library screening can be prepared by PCR, or from the sequences of the desaturase clones provided herein. Oligonucleotides prepared from the desaturase sequences may be used, as well as longer DNA fragments, up to the entire desaturase clone.

For example, jojoba polyadenylated RNA is used to construct a cDNA library in the cloning vector λZAPII/*Eco*RI (Stratagene, San Diego, CA). RNA is isolated from jojoba embryos collected at 80-90 days post-anthesis by isolating polyribosomes using a method initially described by Jackson and Larkins (*Plant Physiol.* (1976) *57*:5-10) and modified by Goldberg *et al.* (*Developmental Biol.* (1981) *83*:201-217). Polysaccharide contaminants in the polyribosomal RNA preparation are removed by running the RNA over a cellulose column (Sigma-cell 50) in high salt buffer (0.5M NaCl, 20mM Tris pH 7.5, 1mM EDTA, 0.1% SDS). The contaminant binds to the column and the RNA is collected in the eluant. The eluant fractions are pooled and the RNA is ethanol precipitated. The precipitated total RNA is then resuspended in a smaller volume and applied to an oligo d(T) cellulose column to isolate the polyadenylated RNA.

The library is constructed using protocols, DNA and bacterial strains as supplied by the manufacturer. Clones are packaged using Gigapack Gold packaging extracts (Stratagene), also according to manufacturer's recommendations. The cDNA library constructed in this manner contins approximately 1 x 10^6 clones with an average cDNA insert size of approximately 400 base pairs.

The jojoba library is plated on *E. coli* XL1-Blue (Stratagene) at a density of approximately 5000pfu/150mm plate to provide approximately 60,000 plaques for screening. Phage are lifted onto duplicate nylon membrane filters as described previously. Filters are prehybridized at 42°C in a hybridization buffer containing 40% formamide, 10X Denhardt's solution, 5X SSC, 0.1% SDS, 50mM EDTA, and 100μg/ml denatured salmon sperm DNA. Hybridization is at 42°C in the same buffer with added nick translated (BRL Nick Translation System) 520 bp *Bgl*II fragment of the *C. tinctorius* desaturase clone described previously. Filters are washed at 50°C in 2X SSC and exposed to X-ray film overnight.

Desaturase clones are detected by hybridization on duplicate filters with the *C. tinctorius* cDNA fragment and

plaque-purified. Positive clones are recovered as plasmids in *E. coli* following manufacturer's directions and materials for *in vivo* excision. Partial, preliminary DNA sequence of a clone, 3-1, is determined and the corresponding amino acid sequence is translated in three frames. In this manner, homology to the *C. tinctorius* desaturase cDNA clone is detected in one reading frame. The preliminary DNA sequence of this jojoba desaturase cDNA fragment is shown in Figure 5 (SEQ ID NO: 43). Also shown is the corresponding translated amino acid sequence in the reading frame having *C. tinctorius* desaturase homology. The jojoba cDNA fragment is approximately 75% homologous at the DNA level and approximately 79% homologous at the amino acid level compared to sequence of the *C. tinctorius* desaturase in this region.

Example 13

Antisense constructs are described which allow for transcription of a reverse copy of the *B. campestris* desaturase cDNA clone in the 5' to 3' orientation of transcription.

Preferential Expression of Antisense Constructs in Embryos

In order to reduce the transcription of a desaturase gene in embryos of *B. napus* or *B. campestris*, constructs may be prepared which allow for production of antisense copies of the desaturase cDNA preferentially in the embryos. Promoter sequences which are desirable to obtain this pattern of expression include, but are not limited to, the ACP, Bce4, and napin 1-2 expression cassettes described in Examples 7, 8, and 9, respectively. It also may be desirable to control the expression of reverse copies of the desaturase cDNA under two different promoters in the same transformed plant to provide for a broader timing of expression of the antisense desaturase DNA. For example, expression from the ACP promoter may begin and end earlier than expression from the napin promoter. Thus, expressing the reverse desaturase from both promoters may result in

the production of the antisense strand of DNA over a longer period of embryo development.

An example of expression of an antisense desaturase gene preferentially in the embryos is provided below. Similar constructs containing the same or a different fragment of the desaturase gene and any of the promoters described above, as well as other promoter regions which may be useful, may also be prepared using gene cloning, insertion, mutation and repair techniques well known to those of ordinary skill in the art.

A. Antisense Desaturase Expression from the ACP Promoter

Construction of pCGN3239 is as follows:

pCGN3235 (Example 12) is digested with *Pvu*II and *Hin*dIII and the *Hin*dIII sticky ends are filled in with Klenow in the presence of 200 µM dNTPs. The 1.2 kb *Pvu*II/*Hin*dIII fragment containing the desaturase coding sequence is gel purified and ligated in the antisense orientation into *Eco*RV-digested pCGN1977 (ACP expression cassette; described in Example 7) to create pCGN3238. The 4.2 kb *Xba*I/*Asp*718 fragment of pCGN3238 containing the antisense desaturase in the ACP cassette is transferred into *Xba*I/*Asp*718-digested pCGN1557 (binary transformation vector; described in Example 7) to create pCGN3239.

B. Antisense Desaturase Expression From The Napin Promoter

Construction of pCGN3240 is as follows: pCGN3235 is digested with *Pvu*II and *Hin*dIII, the sticky ends are blunted, and the resulting fragment is inserted in an anti-sense orientation into pCGN3223 which has been digested with *Sal*I and blunted with Klenow enzyme. The resulting plasmid, pCGN3240 will express an anti-sense desaturase RNA from the napin promoter cassette.

C. Antisense Desaturase Expression From a Dual Promoter Cassette

Construction of pCGN3242 is as follows: An *Asp*718 fragment of pCGN3240 containing the napin 5' and 3' regions surrounding the desaturase sequences is inserted into the

*Asp*718 site of pCGN3239 (a binary vector containing an ACP promoter, antisense desaturase construct) to create pCGN3242.

Constitutive Transcription

A. Binary Vector Construction

1. Construction of pCGP291.

The *Kpn*I, *Bam*HI, and *Xba*I sites of binary vector pCGN1559 (McBride and Summerfelt, *Pl.Mol.Biol.* (1990) *14*: 269-276) are removed by *Asp*718/*Xba*I digestion followed by blunting the ends and recircularization to produce pCGP67. The 1.84 kb *Pst*I/*Hin*dIII fragment of pCGN986 containing the 35S promoter-tml3' cassette is inserted into *Pst*I/*Hin*dIII digested pCGP67 to produce pCGP291.

2. Construction of pCGN986.

The 35S promoter-tml3' expression cassette, pCGN986, contains a cauliflower mosaic virus 35S (CaMV35) promoter and a T-DNA tml 3'-region with multiple restriction sites between them. pCGN986 is derived from another cassette, pCGN206, containing a CaMV35S promoter and a different 3' region, the CaMV region VI 3'-end. The CaMV 35S promoter is cloned as an *Alu*I fragment (bp 7144-7734) (Gardner *et. al., Nucl.Acids Res.* (1981) *9*:2871-2888) into the *Hin*cII site of M13mp7 (Messing, *et. al., Nucl.Acids Res.* (1981) *9*:309-321) to create C614. An *Eco*RI digest of C614 produced the *Eco*RI fragment from C614 containing the 35S promoter which is cloned into the *Eco*RI site of pUC8 (Vieira and Messing, *Gene* (1982) *19*:259) to produce pCGN147.

pCGN148a containing a promoter region, selectable marker (KAN with 2 ATG's) and 3' region, is prepared by digesting pCGN528 with *Bgl*II and inserting the *Bam*HI-*Bgl*II promoter fragment from pCGN147. This fragment is cloned into the *Bgl*II site of pCGN528 so that the *Bgl*II site is proximal to the kanamycin gene of pCGN528.

The shuttle vector used for this construct, pCGN528, is made as follows: pCGN525 is made by digesting a plasmid containing Tn5 which harbors a kanamycin gene (Jorgenson

et. al., Mol. Gen. Genet. (1979) *177*:65) with *Hin*dIII-*Bam*HI and inserting the *Hin*dIII-*Bam*HI fragment containing the kanamycin gene into the *Hin*dIII-*Bam*HI sites in the tetracycline gene of pACYC184 (Chang and Cohen, *J. Bacteriol.* (1978) *134*:1141-1156). pCGN526 was made by inserting the *Bam*HI fragment 19 of pTiA6 (Thomashow *et. al., Cell* (1980) *19*:729-739), modified with *Xho*I linkers inserted into the *Sma*I site, into the *Bam*HI site of pCGN525. pCGN528 is obtained by deleting the small *Xho*I fragment from pCGN526 by digesting with *Xho*I and religating.

pCGN149a is made by cloning the *Bam*HI-kanamycin gene fragment from pMB9KanXXI into the *Bam*HI site of pCGN148a. pMB9KanXXI is a pUC4K variant (Vieira and Messing, *Gene* (1982) *19*:259-268) which has the *Xho*I site missing, but contains a functional kanamycin gene from Tn903 to allow for efficient selection in *Agrobacterium*.

pCGN149a is digested with *Hin*dIII and *Bam*HI and ligated to pUC8 digested with *Hin*dIII and *Bam*HI to produce pCGN169. This removes the Tn903 kanamycin marker. pCGN565 and pCGN169 are both digested with *Hin*dIII and *Pst*I and ligated to form pCGN203, a plasmid containing the CaMV 35S promoter and part of the 5'-end of the Tn5 kanamycin gene (up to the *Pst*I site, Jorgenson *et. al.*, (1979), *supra*). A 3'-regulatory region is added to pCGN203 from pCGN204, an *Eco*RI fragment of CaMV (bp 408-6105) containing the region VI 3' cloned into pUC18 (Yanisch-Perron, *et al., Gene* (1985) *33*:103-119) by digestion with *Hin*dIII and *Pst*I and ligation. The resulting cassette, pCGN206, is the basis for the construction of pCGN986.

The pTiA6 T-DNA tml 3'-sequences are subcloned from the *Bam*19 T-DNA fragment (Thomashow *et al.*, (1980) *supra*) as a *Bam*HI-*Eco*RI fragment (nucleotides 9062 to 12,823, numbering as in Barker *et al., Plant Mol. Biol.* (1982) *2*:335-350) and combined with the pACYC184 (Chang and Cohen (1978), *supra*) origin of replication as an *Eco*RI-*Hin*dIII fragment and a gentamycin resistance marker (from plasmid

pLB41), obtained from D. Figurski) as a *Bam*HI-*Hin*dIII fragment to produce pCGN417.

The unique *Sma*I site of pCGN417 (nucleotide 11,207 of the *Bam*19 fragment) is changed to a *Sac*I site using linkers and the *Bam*HI-*Sac*I fragment is subcloned into pCGN565 to give pCGN971. The *Bam*HI site of pCGN971 is changed to an *Eco*RI site using linkers. The resulting *Eco*RI-*Sac*I fragment containing the tml 3' regulatory sequences is joined to pCGN206 by digestion with *Eco*RI and *Sac*I to give pCGN975. The small part of the Tn5 kanamycin resistance gene is deleted from the 3'-end of the CaMV 35S promoter by digestion with *Sal*I and *Bgl*II, blunting the ends and ligation with *Sal*I linkers. The final expression cassette pCGN986 contains the CaMV 35S promoter followed by two *Sal*I sites, an *Xba*I site, *Bam*HI, *Sma*I, *Kpn*I and the tml 3' region (nucleotides 11207-9023 of the T-DNA).

B. <u>Insertion of Desaturase Sequence</u>

The 1.6 kb *XbaI* fragment from pCGN3235 containing the desaturase cDNA is inserted in the antisense orientation into the *Xba*I site of pCGP291 to produce pCGN3234.

Plant Transformation

The binary vectors containing the expression cassette and the desaturase gene are transformed into *Agrobacterium tumefaciens* strain EHA101 (Hood, *et al.*, *J. Bacteriol.* (1986) *168*:1291-1301) as per the method of Holsters, *et al.*, *Mol. Gen. Genet.* (1978) *163*:181-187. Transformed *B. napus* and/or *Brassica campestris* plants are obtained as described in Example 10.

Analysis of Transgenic Plants

A. <u>Analysis of pCGN3242 Transformed *Brassica campestris* cv. Tobin Plants</u>

Due to the self-incompatibility of *Brassica campestris* cv. Tobin, individual transgenic plants are pollinated using non-transformed Tobin pollen. Because of this, the T2 seeds of a transgenic plant containing the antisense desaturase at one locus would be expected to segregate in a

1:1 ratio of transformed to non-transformed seed. The oil composition of ten individual seeds collected at 26 days post-anthesis from several pCGN3242-transformed plants and one non-transformed control was analyzed by gas chromatography according to the method of Browse, *et al.*, *Anal. Biochem.* (1986) *152*:141-145. One transformant, 3242-T-1, exhibits an oil composition that differed distinctly from controls on preliminary analysis. The control Tobin seeds contained an average of 1.8% 18:0 (range 1.5% - 2.0%) and 52.9% 18:1 (range 48.2% - 57.1%). T2 seeds of 3242-T-1 segregated into two distinct classes. Five seeds contained levels of 18:0 ranging from 1.3% to 1.9% and levels of 18:1 ranging from 42.2% to 58.3%. The other five seeds contained from 22.9% to 26.3% 18:0 and from 19.9% to 26.1% 18:1.

B. Analysis of pCGN3234 Transformed Plants

Some abnormalities have been observed in some transgenic *Brassica napus* cv. Delta and Bingo and *Brassica campestris* cv. Tobin plants containing pCGN3234. These effects could be due to the constitutive expression of antisense desaturase RNA from the 35S promoter or could be due to the transformation/tissue culture regime the plants have been subjected to.

The above results demonstrate the ability to obtain plant Δ-9 desaturases, isolate DNA sequences which encode desaturase activity and manipulate them. In this way, the production of transcription cassettes, including expression cassettes can be produced which allow for production, including specially differentiated cell production of the desired product. A purified *C. tinctorius* desaturase is provided and used to obtain nucleic acid sequences of *C. tinctorius* desaturase. Other plant desaturase sequences are provided such as *R. cummunis*, *B. campestris*, and *S. chinensis*. These sequences as well as desaturase sequences obtained from them may be used to obtain additional desaturease, and so on. And, as described in the application modification of oil composition may b achieved.

All publications and patent applications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claim.

What is claimed is:

1. A recombinant DNA construct comprising a sequence encoding at least a portion of a plant desaturase, said desaturase when mature having activity toward an unsaturated fatty acid substrate.

2. The construct of Claim 1 encoding a biologically active plant desaturase.

3. The construct of Claim 1 wherein said sequence encodes a precursor desaturase.

4. The construct of Claim 1 wherein said sequence encodes a mature desaturase.

5. The construct of Claim 1 wherein said sequence encodes a transit peptide.

6. The construct of Claim 1 comprising a cDNA sequence.

7. The construct of Claim 1 wherein said sequence is joined to a second nucleic acid sequence which is not naturally joined to said first sequence.

8. The construct of Claim 1 comprising, in the 5' to 3' direction of transcription, a transcriptional regulatory region functional in a host cell and said sequence.

9. The construct of Claim 8 further comprising, a translational regulatory region immediately 5' to said sequence and a transcriptional/translational termination regulatory region 3' to said sequence, wherein said regulatory regions are functional in said host cell.

10. The construct of Claim 8 wherein said sequence is a sense sequence.

11. The construct of Claim 8 wherein said sequence is an anti-sense sequence.

12. The construct of Claim 8 wherein said host cell is a plant cell.

13. The construct of Claim 12 wherein said transcriptional initiation region is obtained from a gene preferentially expressed in plant seed tissue during lipid accumulation.

14. The construct of Claim 13 wherein said transcriptional initiation region is selected from the

regulatory region 5' upstream to a structural gene of the group consisting of any one of Bce4, seed ACP Bcg 4-4 and napin 1-2.

15. The construct of Claim 9 wherein said transcriptional termination region is a plant desaturase termination region.

16. The construct of Claim 1 wherein said plant desaturase is a Δ-9 desaturase.

17. The construct of Claim 1 wherein said sequence is obtainable from any one of *C. tinctorius, R. communinis* and *B. campestris*.

18. A method of modifying fatty acid composition in a plant host cell from a given percentage of fatty acid saturation to a different percentage of fatty acid saturation comprising

growing a host plant cell having integrated into its genome a recombinant DNA sequence encoding a plant desaturase under the control of regulatory elements functional in said plant cell during lipid accumulation under conditions which will promote the activity of said regulatory elements.

19. The method of Claim 18 wherein the overexpression of plant desaturase is obtained.

20. The method of Claim 18 wherein the decrease of endogenous plant desaturase is obtained.

21. The method of Claim 18 wherein said regulatory elements function preferentially in plant seed.

22. The method of Claim 20 wherein the percentage of long chain unsaturated fatty acids is increased.

23. A plant cell having a modified level of saturated fatty acids produced according to the method of any one of Claims 18-22.

24. The plant cell of Claim 23 wherein said cell is a *Brassica* plant cell.

25. The plant cell of Claim 23 wherein said cell is *in vivo*.

26. The plant cell of Claim 23 wherein said cell is an oilseed embryo plant cell.

27. A plant seed having a modified level of saturated fatty acids as compared to a seed of said plant having a native level of saturated fatty acids produced according to a method comprising

growing a plant, having integrated into the genome of embryo cells a recombinant DNA sequence encoding a plant desaturase under the control of regulatory elements functional in seed during lipid accumulation, to produce seed under conditions which will promote the activity of said regulatory elements, and

harvesting said seed.

28. The seed of Claim 27 wherein said plant is *Brassica napus*.

29. The seed of claim 27 wherein said seed is an oilseed.

30. The seed of Claim 27 wherein said plant desaturase is a Δ-9 desaturase.

31. A plant seed oil of a plant having an endogenous level of saturated fatty acids comprising a plant seed oil having a modified level of saturated fatty acids.

32. The oil of Claim 31 comprising a *Brassica napus* oil.

33. A plant seed oil separated from an seed produced according to any one of Claims 27-30.

34. A host cell comprising a plant desaturase encoding sequence of any one of Claims 1-17.

35. The cell of Claim 34 wherein said cell is a plant cell.

36. The cell of Claim 35 wherein said plant cell is *in vivo*.

37. The cell of Claim 35 wherein said plant cell is a *Brassica* plant cell.

38. A transgenic host cell comprising an expressed plant desaturase.

39. The cell of Claim 38 wherein said host cell is a plant cell.

40. The cell of Claim 38 wherein said plant desaturase is a Δ-9 desaturase.

41. A method of producing a plant desaturase in a host cell or progeny thereof comprising

growing a host cell or progeny thereof comprising a construct of any one of Claims 1-10 and 12-17 under conditions which will permit the production of said plant desaturase.

42. The method of Claim 41 wherein said host cell is a plant cell and said construct is integrated into the genome of said plant cell.

43. The method of Claim 42 wherein said plant cell is *in vivo*.

44. A host cell comprising a plant desaturase produced according to Claim 41.

45. The cell of Claim 45 wherein said host cell is a plant host cell and said construct is integrated into the genome of said plant cell.

(54) Title: FATTY ACID DESATURASE GENES FROM PLANTS

(57) Abstract

The preparation and use of nucleic acid fragments encoding fatty acid desaturase enzymes are described. The invention permits alteration of plant lipid composition. Chimeric genes incorporating such nucleic acid fragments with suitable regulatory sequences may be used to create transgenic plants with altered levels of unsaturated fatty acids.

TITLE

FATTY ACID DESATURASE GENES FROM PLANTS

FIELD OF THE INVENTION

The invention relates to the preparation and use of nucleic acid fragments encoding fatty acid desaturase enzymes to modify plant lipid composition.

BACKGROUND OF THE INVENTION

Plant lipids have a variety of industrial and nutritional uses and are central to plant membrane function and climatic adaptation. These lipids represent a vast array of chemical structures, and these structures determine the physiological and industrial properties of the lipid. Many of these structures result either directly or indirectly from metabolic processes that alter the degree of unsaturation of the lipid. Different metabolic regimes in different plants produce these altered lipids, and either domestication of exotic plant species or modification of agronomically adapted species is usually required to economically produce large amounts of the desired lipid.

Plant lipids find their major use as edible oils in the form of triacylglycerols. The specific performance and health attributes of edible oils are determined largely by their fatty acid composition. Most vegetable oils derived from commercial plant varieties are composed primarily of palmitic (16:0), stearic (18:0), oleic (18:1), linoleic (18:2) and linolenic (18:3) acids. Palmitic and stearic acids are, respectively, 16- and 18-carbon-long, saturated fatty acids. Oleic, linoleic, and linolenic acids are 18-carbon-long, unsaturated fatty acids containing one, two, and three double bonds, respectively. Oleic acid is referred to as a mono-unsaturated fatty acid, while linoleic and linolenic acids are referred to as poly-unsaturated fatty acids. The relative amounts of saturated and

unsaturated fatty acids, in commonly used, edible vegetable oils are summarized below (Table 1):

TABLE 1

Percentages of Saturated and Unsaturated Fatty Acids in the Oils of Selected Oil Crops

	Saturated	Mono-unsaturated	Poly-unsaturated
Canola	6%	58%	36%
Soybean	15%	24%	61%
Corn	13%	25%	62%
Peanut	18%	48%	34%
Safflower	9%	13%	78%
Sunflower	9%	41%	51%
Cotton	30%	19%	51%

Many recent research efforts have examined the role that saturated and unsaturated fatty acids play in reducing the risk of coronary heart disease. In the past, it was believed that mono-unsaturates, in contrast to saturates and poly-unsaturates, had no effect on serum cholesterol and coronary heart disease risk. Several recent human clinical studies suggest that diets high in mono-unsaturated fat and low in saturated fat may reduce the "bad" (low-density lipoprotein) cholesterol while maintaining the "good" (high-density lipoprotein) cholesterol (Mattson et al., Journal of Lipid Research (1985) 26:194-202).

A vegetable oil low in total saturates and high in mono-unsaturates would provide significant health benefits to consumers as well as economic benefits to oil processors. As an example, canola oil is considered a very healthy oil. However, in use, the high level of poly-unsaturated fatty acids in canola oil renders the oil unstable, easily oxidized, and susceptible to development of disagreeable odors and flavors (Gailliard, 1980, Vol. 4, pp. 85-116 In: Stumpf, P. K., Ed., The Biochemistry of Plants, Academic Press, New

York). The levels of poly-unsaturates may be reduced by hydrogenation, but the expense of this process and the concomitant production of nutritionally questionable trans isomers of the remaining unsaturated fatty acids reduces the overall desirability of the hydrogenated oil (Mensink et al., New England J. Medicine (1990) N323: 439-445). Similar problems exist with soybean and corn oils.

For specialized uses, high levels of poly-unsaturates can be desirable. Linoleate and linolenate are essential fatty acids in human diets, and an edible oil high in these fatty acids can be used for nutritional supplements, for example in baby foods. Linseed oil, derived from the Flax plant (Linum usitatissimum), contains over 50% linolenic acid and has widespread use in domestic and industrial coatings since the double bonds of the fatty acids react rapidly with oxygen to polymerize into a soft and flexible film. Although the oil content of flax is comparable to canola (around 40% dry weight of seed), high yields are only obtained in warm temperatures or subtropical climates. In the USA flax is highly susceptible to rust infection. It will be commercially useful if a crop such as soybean or canola could be genetically transformed by the appropriate desaturase gene(s) to synthesize oils with a high linolenic acid content.

Mutation-breeding programs have met with some success in altering the levels of poly-unsaturated fatty acid levels found in the edible oils of agronomic species. Examples of commercially grown varieties are high (85%) oleic sunflower and low (2%) linolenic flax (Knowles, (1980) pp. 35-38 In: Applewhite, T. H., Ed., World Conference on Biotechnology for the Fats and Oils Industry Proceedings, American Oil Chemists' Society). Similar commercial progress with the other plants shown

in Table 1 has been largely elusive due to the difficult nature of the procedure and the pleiotropic effects of the mutational regime on plant hardiness and yield potential.

The biosynthesis of the major plant lipids has been the focus of much research (Browse et al., Ann. Rev. Plant Physiol. Mol. Biol. (1991) 42:467-506). These studies show that, with the notable exception of the soluble stearoyl-acyl carrier protein desaturase, the controlling steps in the production of unsaturated fatty acids are largely catalyzed by membrane-associated fatty acid desaturases. Desaturation reactions occur in plastids and in the endoplasmic reticulum using a variety of substrates including galactolipids, sulfolipids, and phospholipids. Genetic and physiological analyses of Arabidopsis thaliana nuclear mutants defective in various fatty acid desaturation reactions indicates that most of these reactions are catalyzed by enzymes encoded at single genetic loci in the plant. The analyses show further that the different defects in fatty acid desaturation can have profound and different effects on the ultra-structural morphology, cold sensitivity, and photosynthetic capacity of the plants (Ohlrogge, et al., Biochim. Biophys. Acta (1991) 1082:1-26). However, biochemical characterization of the desaturase reactions has been meager. The instability of the enzymes and the intractability of their proper assay has largely limited researchers to investigations of enzyme activities in crude membrane preparations. These investigations have, however, demonstrated the role of delta-12 desaturase and delta-15 desaturase activities in the production of linoleate and linolenate from 2-oleoyl-phosphatidyl-choline and 2-linoleoyl-phosphatidylcholine, respectively (Wang et al., Plant Physiol. Biochem.

(1988) 26:777-792). Thus, modification of the activities of these enzymes represents an attractive target for altering the levels of lipid unsaturation by genetic engineering.

Genes from plants for stearoyl-acyl carrier protein desaturase, the only soluble fatty acid desaturase known, have been described (Thompson, et al., Proc. Natl. Acad. Sci. U.S.A. (1991) 88:2578-2582; Shanklin et al., Proc. Natl. Acad. Sci. USA (1991) 88:2510-2514). Stearoyl-coenzyme-A desaturase genes from yeast, rat, and mice have also been described (Stukey, et al., J. Biol. Chem.(1990) 265:20144-20149; Thiede, et al., J. Biol. Chem. (1986) 261:13230-13235; Kaestner, et al., J. Biol. Chem. (1989) 264:14755-1476). No evidence exists in the public art that describes the isolation of fatty acid desaturases other than stearoyl-ACP desaturases from higher plants or their corresponding genes. A fatty acid desaturase gene from the cyanobacterium, Synechocystis PCC 6803, has also been described (Wada, et al., Nature (1990) 347:200-203). This gene encodes a fatty acid desaturase, designated des A, that catalyzes the conversion of oleic acid at the 1 position of galactolipids to linoleic acid. However, these genes have not proven useful for isolating plant fatty acid desaturases other than stearoyl-ACP desaturase via sequence-dependent protocols, and the present art does not indicate how to obtain plant fatty acid desaturases other than stearoyl-ACP desaturases or how to obtain fatty acid desaturase-related enzymes. Thus, the present art does not teach how to obtain glycerolipid desaturases from plants. Furthermore, there is no evidence that a method to control the nature and levels of unsaturated fatty acids in plants using nucleic acids encoding fatty acid desaturases other than stearoyl-ACP desaturase is known in the art.

The biosynthesis of the minor plant lipids has been less well studied. While hundreds of different fatty acids have been found, many from the plant kingdom, only a tiny fraction of all plants have been surveyed for their lipid content (Gunstone, et al., Eds., (1986) The Lipids Handbook, Chapman and Hall Ltd., Cambridge). Accordingly, little is known about the biosynthesis of these unusual fatty acids and fatty acid derivatives. Interesting chemical features found in such fatty acids include, for example, allenic and conjugated double bonds, acetylenic bonds, trans double bonds, multiple double bonds, and single double bonds in a wide number of positions and configurations along the fatty acid chain. Similarly, many of the structural modifications found in unusual lipids (e.g., hydroxylation, epoxidation, cyclization, etc.) are probably produced via further metabolism following chemical activation of the fatty acid by desaturation or they involve a chemical reaction that is mechanistically similar to desaturation. For example, evidence for the mechanism of hydroxylation of fatty acids being part of a general mechanism of enzyme-catalyzed desaturation in eukaryotes has been obtained by substituting a sulfur atom in the place of carbon at the delta-9 position of stearic acid. When incubated with yeast cell extracts the thiostearate was converted to a 9-sulfoxide (Buist et al. (1987) Tetrahedron Letters 28:857-860). This sulfoxidation was specific for sulfur at the delta-9 position and did not occur in a yeast delta-9-desaturase deficient mutant (Buist & Marecak (1991) Tetrahedron Letters 32:891-894). The 9-sulfoxide is the sulfur analogue of 9-hydroxyoctadecastearate, the proposed intermediate of stearate desaturation. Thus fatty-acid desaturase cDNAs may serve as useful probes for cDNAs encoding fatty-acid hydroxylases and other cDNAs which encode enzymes with

reaction mechanisms similar to fatty-acid desaturation. Many of these fatty acids and derivatives having such features within their structure could prove commercially useful if an agronomically viable species could be induced to synthesize them by introduction of a gene encoding the appropriate desaturase.

SUMMARY OF THE INVENTION

Applicants have discovered a means to control the nature and levels of unsaturated fatty acids in plants. Nucleic acid fragments from glycerolipid desaturase cDNAs or genes are used to create chimeric genes. The chimeric genes may be used to transform various plants to modify the fatty acid composition of the plant or the oil produced by the plant. More specifically, one embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a plant delta-15 fatty acid desaturase or a fatty acid desaturase-related enzyme with an amino acid identity of 50%, 65%, 90% or greater to the polypeptide encoded by SEQ ID NOS:1, 4, 6, 8, 10, 12, 14, or 16. The isolated fragment in these embodiments is isolated froma plant selected from the group consisting of soybean, oilseed Brassica species, Arabidopsis thaliana and corn.

Another embodiment of this invention involves the use of these nucleic acid fragments in sequence-dependent protocols. Examples include use of the fragments as hybridization probes to isolate other glycerolipid desaturase cDNAs or genes. A related embodiment involves using the disclosed sequences for amplification of DNA fragments encoding other glycerolipid desaturases.

Another aspect of this invention involves chimeric genes capable of causing altered levels of the linolenic acid in a transformed plant cell, the gene comprising nucleic acid fragments encoding encoding a plant

delta-15 fatty acid desaturase or a fatty acid desaturase-related enzyme with an amino acid identity of 50%, 65%, 90% or greater to the polypeptide encoded by SEQ ID NOS:1, 4, 6, 8, 10, 12, 14, or 16 operably linked in suitable orientation to suitable regulatory sequences. Preferred are those chimeric genes which incorporate nucleic acid fragments encoding delta-15 fatty acid desaturase cDNAs or genes. Plants and oil from seeds of plants containing the chimeric genes described are also claimed.

Yet another embodiment of the invention involves a method of producing seed oil containing altered levels of linolenic (18:3) acid comprising: (a) transforming a plant cell with a chimeric gene described above; (b) growing fertile plants from the transformed plant cells of step (a); (c) screening progeny seeds from the fertile plants of step (b) for the desired levels of linolenic (18:3) acid, and (d) processing the progeny seed of step (c) to obtain seed oil containing altered levels of the unsaturated fatty acids. Preferred plant cells and oils are derived from soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, coconut, flax, oil palm, and corn. Preferred methods of transforming such plant cells would include the use of Ti and Ri plasmids of Agrobacterium, electroporation, and high-velocity ballistic bombardment.

The invention also is embodied in a method of breeding plant species to obtain altered levels of polyunsaturated fatty acids, specifically linolenic (18:3) acid in seed oil of oil-producing plants. This method involves (a) making a cross between two varieties of an oilseed plant differing in the linolenic acid trait; (b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and (c)

hybridizing the Southern blot with the radiolabeled nucleic acid fragments encoding the claimed glycerolipid desaturases.

The invention is also embodied in a method of RFLP mapping that uses the isolated *Arabidopsis thaliana* delta-15 desaturase sequences described herein.

The invention is also embodied in plants capable of producing altered levels of glycerolipid desaturase by virtue of containing the chimeric genes described herein. Further, the invention is embodied by seed oil obtained from such plants.

The invention is also embodied in a method of RFLP mapping ina genomic RFLP marker comprising(a) making a cross between two varieties of plants; (b)making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and (c) hybridizing the Southern blot with a radiolabelled nucleic acid fragments of the claimed fragments.

The invention is also embodied in a method to isolate nucleic acid fragments encoding fatty acid desaturases and fatty acid desaturase-related enzymes, comprising (a)comparing SEQ ID NOS:2, 5, 7, 9, 11, 13, 15 and 17 with other fatty acid desaturase polypeptide sequences; (b) identifying the conserved sequence(s) of 4 or more amino acids obtained in step a; (c) making region-specific nucleotide probe(s) or oligomer(s) based on the conserved sequences identified in step b; and d) using the nucleotide probe(s) or oligomers(s) of step c to isolate sequences encoding fatty acid desaturases and fatty-acid desaturase-related enzymes by sequence-dependent protocols. The product of the method of isolation method described is also part of the invention.

BRIEF DESCRIPTION OF THE SEQUENCE DESCRIPTIONS

The invention can be more fully understood from the following detailed description and the Sequence Descriptions which form a part of this application. The Sequence Descriptions contain the one letter code for nucleotide sequence characters and the three letter code for amino acids in conformity with the IUPAC-IUB standard described in Nucleic Acids Research 13:3021-3030 (19085) and 37 C.F.R. 1.822 which are incorporated herein by reference.

SEQ ID NO:1 shows the complete 5' to 3' nucleotide sequence of 1350 base pairs of the *Arabidopsis* cDNA which encodes delta-15 desaturase in plasmid pCF3. Nucleotides 46 to 48 are the putative initiation codon of the open reading frame (nucleotides 46 to 1206). Nucleotides 1204 to 1206 are the termination codon. Nucleotides 1 to 45 and 1207 to 1350 are the 5' and 3' untranslated nucleotides, respectively. The 386 amino acid protein sequence in SEQ ID NO:1 is that deduced from the open reading frame.

SEQ ID NO:2 is the deduced peptide of the open-reading frame of SEQ ID NO:1.

SEQ ID NO:3 is a partial nucleotide sequence of the *Arabidopsis* genomic DNA insert in plasmid pF1 which shows the genomic sequence in the region of the *Arabidopsis* genome that encodes delta-15 desaturase. Nucleotides 68-255 are identical to nucleotides 1-188 of SEQ ID NO:1. Nucleotides 47 to 49 and 56 to 58 are termination codons in the same reading frame as the open reading frame in SEQ ID NO:1.

SEQ ID NO:4 shows the 5' to 3' nucleotide sequence of the insert in plasmid pACF2-2 of 1525 base pairs of the *Arabidopsis thaliana* cDNA that encodes a plastid delta-15 fatty acid desaturase. Nucleotides 10-12 and nucleotides 1348 to 1350 are, respectively, the putative

initiation codon and the termination codon of the open reading frame (nucleotides 10 to 1350). Nucleotides 1 to 9 and 1351 to 1525 are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:5 is the deduced peptide of the open reading frame of SEQ ID NO:4.

SEQ ID NO:6 shows the complete 5' to 3' nucleotide sequence of 1336 base pairs of the Brassica napus seed cDNA, found in plasmid pBNSF3-2, which encodes a microsomal delta-15 glycerolipid desaturase. Nucleotides 79 to 82 are the putative initiation codon of the open reading frame (nucleotides 79 to 1212). Nucleotides 1210 to 1212 are the termination codon. Nucleotides 1 to 78 and 1213 to 1336 are the 5' and 3' unstranslated nucleotides respectively.

SEQ ID NO:7 is the deduced peptide of the open reading frame of SEQ ID NO:6.

SEQ ID NO:8 is the complete 5' to 3' nucleotide sequence of 1416 base pairs of the Brassica napus seed cDNA found in plasmid pBNSFd-2 which encodes a plastid delta-15 glycerolipid desaturase. Nucleotides 1 to 1215 correspond to a continuous open reading frame of 404 amino acids. Nucleotides 1213 to 1215 are the termination codon. Nucleotides 1215 to 1416 are the 3' untranslated nucleotides.

SEQ ID NO:9 is the deduced peptide of the open reading frame of SEQ ID NO:8.

SEQ ID NO:10 is the complete nucleotide sequence of the soybean (glycine max) microsomal delta-15 desaturase cDNA, found in plasmid pXF1, which the 2184 nucleotides of this sequence contain·both the coding sequence and the 5' and 3' non-translated regions of the cDNA. Nucleotides 855 to 857 are the putative initiation codon of the open reading frame (nucleotides 855 to 2000). Nucleotides 1995 to 1997 are the termination codon.

Nucleotides 1 to 854 and 1998 to 2184 are the 5' and 3' unstranslated nucl otides respectively. The 380 amino acid protein sequence in SEQ ID NO:7 is that deduced from the open reading frame.

SEQ ID NO:11 is the deduced peptide of the open reading frame in SEQ ID NO:10.

SEQ ID NO:12 is the complete 5' to 3' nucleotide sequence of 1676 base pairs of the soybean (<u>Glycine max</u>) seed cDNA found in plasmid pSFD-118bwp which encodes a soybean plastid delta-15 desaturase. Nucleotides 169 to 1530 correspond to a continuous open reading frame of 453 amino acids. Nucleotides 169 to 171 are the putative initiation codon of the open reading frame. Nucleotides 1528 to 1530 are the termination codon. Nucleotides 1531 to 1676 are the 3' untranslated nucleotides. Nucleotides 169 to 382 encode the putative plastid transit peptide, based on comparison of the deduced peptide with the soybean microsomal delta-15 peptide.

SEQ ID NO:13 is the deduced peptide of the open reading frame in SEQ ID NO:12.

SEQ ID NO:14 is the complete nucleotide sequence of a 396 bp polymerase chain reaction product derived from corn seed mRNA that is found in the insert of plasmid pPCR20. Nucleotides 1 to 31 and 364 to 396 correspond to the amplification primers described in SEQ ID NO:18 and SEQ ID NO:19, respectively. Nucleotides 31 to 363 encode an internal region of a corn seed delta-15 desaturase that is 61.9% identical to the region between amino acids 137 and 249 of the Brassica napus delta-15 desaturase peptide sequence shown in SEQ ID NO:7.

SEQ ID NO:15 is the deduced amino acid sequence of SEQ ID NO:14.

SEQ ID NO:16 shows the partial composite 5' to 3' nucleotide sequence of 472 bp derived from the inserts

in plasmids pFadx-2 and pYacp7 for Arabidopsis thaliana cDNA that encodes a plastid delta-15 fatty acid desaturase. Nucleotides 2-4 and nucleotides 468 to 470 are, respectively, the first and the last codons in the open reading frame.

SEQ ID NO:17 is deduced partial peptide sequence of the open reading frame in SEQ ID NO:16.

SEQ ID NO:18 One hundred and twenty eight fold degenerate sense 31-mer PCR primer. Nucleotides 1 to 8 correspond to the Bam H1 restriction enzyme recognition sequence. Nucleotides 9 to 137 correspond to amino acid residues 130 to 137 of SEQ ID NO:6 with a deoxyinosine base at nucleotide 11.

SEQ ID NO:19 Two thousand and forty eight-fold degenerate antisense 35-mer PCR primer. Nucleotides 1 to 8 correspond to the Bam H1 restriction enzyme recognition sequence. Nucleotides 9 to 35 correspond to amino acid residues 249 to 256 of SEQ ID NO:6 with a deoxyinosine base at nucleotide 15.

SEQ ID NO:20 Sixteen-fold degenerate sense 36-mers made to amino acid residues 97-108 in SEQ ID NO:2.

SEQ ID NO:21 Sixteen-fold degenerate sense 36-mers made to amino acid residues 97-108 in SEQ ID NO:2.

SEQ ID NO:22 Seventy two-fold degenerate sense 18-mers made to amino acid residues 100-105 in SEQ ID NO:2.

SEQ ID NO:23 Seventy two-fold degenerate sense 18-mers made to amino acid residues 100-105 in SEQ ID NO:2.

SEQ ID NO:24 Seventy two-fold degenerate antisense 18-mers made to amino acid residues 299-304 in SEQ ID NO:2.

SEQ ID NO:25 Seventy two-fold degenerate antisense 18-mers made to amino acid residues 299-304 in SEQ ID NO:2.

SEQ ID NO:26 S venty two-fold degenerate antisense 18-mers made to amino acid residues 304-309 in SEQ ID NO:2.

SEQ ID NO:27 Seventy two-fold degenerate antisense 18-mers made to amino acid residues 304-309 in SEQ ID NO:2.

SEQ ID NO:28 Sixteen-fold degenerate sense 36-mers made to amino acid residues 97-108 in SEQ ID NO:2.

SEQ ID NO:29 Sixteen-fold degenerate sense 36-mers made to amino acid residues 97-108 in SEQ ID NO:2.

SEQ ID NO:30 Sixty four-fold degenerate antisense 38-mers made to amino acid residues 299-311 in SEQ ID NO:2.

SEQ ID NO:31 Sixty four-fold degenerate antisense 38-mers made to amino acid residues 299-311 in SEQ ID NO:2.

SEQ ID NO:32 A 135-mer made as an antisense strand to amino acid residues 97-141 in SEQ ID NO:2.

DETAILED DESCRIPTION OF THE INVENTION

Applicants have isolated nucleic acid fragments that encode plant fatty acid desaturases and that are useful in modifying fatty acid composition in oil-producing species by transformation.

Thus, transfer of the nucleic acid fragments of the invention or a part thereof that encodes a functional enzyme, along with suitable regulatory sequences that direct the transciption of their mRNA, into a living cell will result in the production or over-production of plant fatty acid desaturases and will result in increased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transciption of their antisense RNA, into plants will result in the

inhibition of expression of the endogenous fatty acid desaturase that is substantially homologous with the transferred nucleic acid fragment and will result in decreased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transciption of their mRNA, into plants may result in inhibition by cosuppression of the expression of the endogenous fatty acid desaturase gene that is substantially homologous with the transferred nucleic acid fragment and may result in decreased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

The nucleic acid fragments of the invention can also be used as restriction fragment length polymorphism (RFLP) markers in Arabidopsis genetic mapping and plant breeding programs.

The nucleic acid fragments of the invention or oligomers derived therefrom can also be used to isolate other related glycerolipid desaturase genes using DNA, RNA, or a library of cloned nucleotide sequences from the same or different species by well known sequence-dependent protocols, including, for example, methods of nucleic acid hybridization and amplification by the polymerase chain reaction.

Definitions

In the context of this disclosure, a number of terms shall be used. The term "fatty acid desaturase" used herein refers to an enzyme which catalyzes the breakage of a carbon-hydrogen bond and the introduction of a carbon-carbon double bond into a fatty acid molecule. The fatty acid may be free or esterified to another molecule including, but not limited to, acyl-carrier protein, coenzyme A, sterols and the glycerol

moiety of glycerolipids. The term "glycerolipid desaturases" used herein ref rs to a subset of the fatty acid desaturases that act on fatty acyl moieties esterified to a glycerol backbone. "Delta-12 desaturase" refers to a fatty acid desaturase that catalyzes the formation of a double bond between carbon positions 6 and 7 (numbered from the methyl end), (i.e., those that correspond to carbon positions 12 and 13 (numbered from the carbonyl carbon) of an 18 carbon-long fatty acyl chain or carbon positions 10 and 11 (numbered from the carbonyl carbon) of a 16 carbon-long fatty acyl chain). "Delta-15 desaturase" refers to a fatty acid desaturase that catalyzes the formation of a double bond between carbon positions 3 and 4 (numbered from the methyl end), (i.e., those that correspond to carbon positions 15 and 16 (numbered from the carbonyl carbon) of an 18 carbon-long fatty acyl chain and carbon positions 13 and 14 (numbered from the carbonyl carbon) of a 16 carbon-long fatty acyl chain). Examples of fatty acid desaturases include, but are not limited to, the microsomal delta-12 and delta-15 desaturases that act on phosphatidylcholine lipid substrates; the chloroplastic delta-12 and delta-15 desaturases that act on phosphatidyl glycerol and galactolipids; and other desaturases that act on such fatty acid substrates such as phospholipids, galactolipids, and sulfolipids. "Microsomal desaturase" refers to the cytoplasmic location of the enzyme, while "chloroplast desaturase" and "plastid desaturase" refer to the plastid location of the enzyme. These fatty acid desaturases may be found in a variety of organisms including, but not limited to, higher plants, diatoms, and various eukaryotic and prokaryotic microorganisms such as fungi and photosynthetic bacteria and algae. The term "homologous fatty acid desaturases" refers to fatty acid

desaturases that catalyze the same desaturation on the same lipid substrate. Thus, microsomal delta-15 desaturases, even from different plant species, are homologous fatty acid desaturases. The term "heterologous fatty acid desaturases" refers to fatty acid desaturases that catalyze desaturations at different positions and/or on different lipid substrates. Thus, for example, microsomal delta-12 and delta-15 desaturases, which act on phosphatidylcholine lipids, are heterologous fatty acid desaturases, even when from the same plant. Similarly, microsomal delta-15 desaturase, which acts on phosphatidylcholine lipids, and chloroplast delta-15 desaturase, which acts on galactolipids, are heterologous fatty acid desaturases, even when from the same plant. It should be noted that these fatty acid desaturases have never been isolated and characterized as proteins. Accordingly the terms such as "delta-12 desaturase" and "delta-15 desaturase" are used as a convenience to describe the proteins encoded by nucleic acid fragments that have been isolated based on the phenotypic effects caused by their disruption. The term "fatty acid desaturase-related enzyme" refers to enzymes whose catalytic product may not be a carbon-carbon double bond but whose mechanism of action is similar to that of a fatty acid desaturase (that is, catalysis of the displacement of a carbon-hydrogen bond of a fatty acid chain to form a fatty-hydroxyacyl intermediate or end-product). This term is different from "related fatty acid desaturases", which refers to structural similarities between fatty acid desaturases.

The term "nucleic acid" refers to a large molecule which can be single-stranded or double-stranded, composed of monomers (nucleotides) containing a sugar, a phosphate and either a purine or pyrimidine. A "nucleic

acid fragment" is a fraction of a given nucleic acid molecule. In higher plants, deoxyribonucleic acid (DNA) is the genetic material while ribonucleic acid (RNA) is involved in the transfer of the information in DNA into proteins. A "genome" is the entire body of genetic material contained in each cell of an organism. The term "nucleotide sequence" refers to the sequence of DNA or RNA polymers, which can be single- or double-stranded, optionally containing synthetic, non-natural or altered nucleotide bases capable of incorporation into DNA or RNA polymers. The term "oligomer" refers to short nucleotide sequences, usually up to 150 bases long. "Region-specific nucleotide probes" refers to isolated nucleic acid fragments derived from a cDNA or gene using a knowledge of the amino acid regions conserved between different fatty-acid desaturases which may be used to isolate cDNAS or genes for other fatty-acid desaturases or fatty acid desaturase-related enzymes using sequence dependent protocols. As used herein, the term "homologous to" refers to the relatedness between the nucleotide sequence of two nucleic acid molecules or between the amino acid sequences of two protein molecules. Estimates of such homology are provided by either DNA-DNA or DNA-RNA hybridization under conditions of stringency as is well understood by those skilled in the art (Hames and Higgins, Eds. (1985) Nucleic Acid Hybridisation, IRL Press, Oxford, U.K.); or by the comparison of sequence similarity between two nucleic acids or proteins, such as by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453). As used herein, "substantially homologous" refers to nucleotide sequences that have more than 90% overall identity at the nucleotide level with the coding region of the claimed sequence, such as genes and pseudo-genes corresponding to the coding

regions. The nucleic acid fragments described herein include molecules which comprise possible variations, both man-made and natural, such as but not limited to (a) those that involve base changes that do not cause a change in an encoded amino acid, or (b) which involve base changes that alter an amino acid but do not affect the functional properties of the protein encoded by the DNA sequence, (c) those derived from deletions, rearrangements, amplifications, random or controlled mutagenesis of the nucleic acid fragment, and (d) even occasional nucleotide sequencing errors.

"Gene" refers to a nucleic acid fragment that expresses a specific protein, including regulatory sequences preceding (5' non-coding) and following (3' non-coding) the coding region. "Fatty acid desaturase gene" refers to a nucleic acid fragment that expresses a protein with fatty acid desaturase activity. "Native" gene refers to an isolated gene with its own regulatory sequences as found in nature. "Chimeric gene" refers to a gene that comprises heterogeneous regulatory and coding sequences not found in nature. "Endogenous" gene refers to the native gene normally found in its natural location in the genome and is not isolated. A "foreign" gene refers to a gene not normally found in the host organism but that is instead introduced by gene transfer. "Pseudo-gene" refers to a genomic nucleotide sequence that does not encode a functional enzyme.

"Coding sequence" refers to a DNA sequence that codes for a specific protein and excludes the non-coding sequences. It may constitute an "uninterrupted coding sequence", i.e., lacking an intron or it may include one or more introns bounded by appropriate splice junctions. An "intron" is a nucleotide sequence that is transcribed in the primary transcript but that is removed through cleavage and re-ligation of the RNA within the cell to

create the mature mRNA that can be translated into a protein.

"Initiation codon" and "termination codon" refer to a unit of three adjacent nucleotides in a coding sequence that specifies initiation and chain termination respectively, of protein synthesis (mRNA translation). "Open reading frame" refers to the coding sequence uninterrupted by introns between initiation and termination codons that encodes an amino acid sequence.

"RNA transcript" refers to the product resulting from RNA polymerase-catalyzed transcription of a DNA sequence. When the RNA transcript is a perfect complementary copy of the DNA sequence, it is referred to as the primary transcript or it may be a RNA sequence derived from posttranscriptional processing of the primary transcript and is referred to as the mature RNA. "Messenger RNA (mRNA)" refers to the RNA that is without introns and that can be translated into protein by the cell. "cDNA" refers to a double-stranded DNA that is complementary to and derived from mRNA. "Sense" RNA refers to RNA transcript that includes the mRNA. "Antisense RNA" refers to a RNA transcript that is complementary to all or part of a target primary transcript or mRNA and that blocks the expression of a target gene by interfering with the processing, transport and/or translation of its primary transcript or mRNA. The complementarity of an antisense RNA may be with any part of the specific gene transcript, i.e., at the 5' non-coding sequence, 3' non-coding sequence, introns, or the coding sequence. In addition, as used herein, antisense RNA may contain regions of ribozyme sequences that increase the efficacy of antisense RNA to block gene expression. "Ribozyme" refers to a catalytic RNA and includes sequence-specific endoribonucleases.

As used herein, "suitable regulatory sequences" refer to nucleotide sequences in native or chimeric genes that are located upstream (5'), within, and/or downstream (3') to the nucleic acid fragments of the invention, which control the expression of the nucleic acid fragments of the invention. The term "expression", as used herein, refers to the transcription and stable accumulation of the sense (mRNA) or the antisense RNA derived from the nucleic acid fragment(s) of the invention that, in conjunction with the protein apparatus of the cell, results in altered levels of the fatty acid desaturase(s). Expression or overexpression of the gene involves transcription of the gene and translation of the mRNA into precursor or mature fatty acid desaturase proteins. "Antisense inhibition" refers to the production of antisense RNA transcripts capable of preventing the expression of the target protein. "Overexpression" refers to the production of a gene product in transgenic organisms that exceeds levels of production in normal or non-transformed organisms. "Cosuppression" refers to the expression of a foreign gene which has substantial homology to an endogenous gene resulting in the suppression of expression of both the foreign and the endogenous gene. "Altered levels" refers to the production of gene product(s) in transgenic organisms in amounts or proportions that differ from that of normal or non-transformed organisms.

"Promoter" refers to a DNA sequence in a gene, usually upstream (5') to its coding sequence, which controls the expression of the coding sequence by providing the recognition for RNA polymerase and other factors required for proper transcription. In artificial DNA constructs promoters can also be used to transcribe antisense RNA. Promoters may also contain DNA sequences that are involved in the binding of

protein factors which control the effectiveness of transcription initiation in response to physiological or developmental conditions. It may also contain enhancer elements. An "enhancer" is a DNA sequence which can stimulate promoter activity. It may be an innate element of the promoter or a heterologous element inserted to enhance the level and/or tissue-specificity of a promoter. "Constitutive promoters" refers to those that direct gene expression in all tissues and at all times. "Tissue-specific" or "development-specific" promoters as referred to herein are those that direct gene expression almost exclusively in specific tissues, such as leaves or seeds, or at specific development stages in a tissue, such as in early or late embryogenesis, respectively.

The "3' non-coding sequences" refers to the DNA sequence portion of a gene that contains a polyadenylation signal and any other regulatory signal capable of affecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by affecting the addition of polyadenylic acid tracts to the 3' end of the mRNA precursor.

The term "Transit Peptide" refers to the N-terminal extension of a protein that serves as a signal for uptake and transport of that protein into an organelle such as a plastid or mitochondrion.

"Transformation" herein refers to the transfer of a foreign gene into the genome of a host organism and its genetically stable inheritance. "Restriction fragment length polymorphism" refers to different sized restriction fragment lengths due to altered nucleotide sequences in or around variant forms of genes. "Fertile" refers to plants that are able to propagate sexually.

"Oil-producing species" herein refers to plant species which produce and store triacylglycerol in specific organs, primarily in seeds. Such species include soybean (Glycine max), rapeseed and canola (including Brassica napus, B. campestris), sunflower (Helianthus annus), cotton (Gossypium hirsutum), corn (Zea mays), cocoa (Theobroma cacao), safflower (Carthamus tinctorius), oil palm (Elaeis guineensis), coconut palm (Cocos nucifera), flax (Linum usitatissimum), castor (Ricinus communis) and peanut (Arachis hypogaea). The group also includes non-agronomic species which are useful in developing appropriate expression vectors such as tobacco, rapid cycling Brassica species, and Arabidopsis thaliana, and wild species which may be a source of unique fatty acids.

"Sequence-dependent protocols" refer to techniques that rely on a nucleotide sequence for their utility. Examples of sequence-dependent protocols include, but are not limited to, the methods of nucleic acid and oligomer hybridization and methods of DNA and RNA amplification such as are exemplified in various uses of the polymerase chain reaction. "PCR product" refers to the DNA product obtained through polymerase chain reaction.

Various solutions used in the experimental manipulations are referred to by their common names such as "SSC", "SSPE", "Denhardt's solution", etc. The composition of these solutions may be found by reference to Appendix B of Sambrook, et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press).

T-DNA Mutagenesis and Identification of an
Arabidopsis Mutant Defective in Delta-15 Desaturation

In T-DNA mutagenesis (Feldmann, et al., Science (1989) 243:1351-1354), the integration of T-DNA in the genome can interrupt normal expression of the gene at or near the site of the integration. If the resultant mutant phenotype can be detected and shown genetically to be tightly linked to the T-DNA insertion, then the "tagged" locus and its wild type counterpart can be readily isolated by molecular cloning by one skilled in the art.

Arabidopsis thaliana seeds were transformed by *Agrobacterium tumefaciens* C58C1rif strain harboring the avirulent Ti-plasmid pGV3850::pAK1003 that has the T-DNA region between the left and right T-DNA borders replaced by the origin of replication region and ampicillin resistance gene of plasmid pBR322, a bacterial kanamycin resistance gene, and a plant kanamycin resistance gene (Feldmann, et al., Mol. Gen. Genetics (1987) 208:1-9). Plants from the treated seeds were self-fertilized and the resultant progeny seeds, germinated in the presence of kanamycin, were self-fertilized to give rise to a population, designated T3, that was segregating for T-DNA insertions. T3 seeds from approximately 6000 T2 plants were analyzed for fatty acid composition. One line, designated 3707, showed a reduced level of linolenic acid (18:3). One more round of self-fertilization of mutant line 3707 produced T4 progeny seeds. The ratio of 18:2/18:3 in seeds of the homogyzous mutant in T4 population was ca. 14; this ratio is ca 1.8 and ca. 23, respectively, in wild-type Arabidopsis and Arabidopsis fad 3 mutant [Lemieux et al. (1990) Theor. App. Gen. 80:234-240] obtained via chemical mutagenesis. These seeds were planted and 263 individual plants were analyzed for the presence of

nopaline in leaf extracts. T5 seeds from these plants were furth r analyzed for fatty acid composition and the ability to germinate in the presence of kanamycin. The mutant fatty acid phenotype was found to segregate in a 1:2:1 ratio, as was germinability on kanamycin. Nopaline was found in all plants with an altered fatty acid phenotype, but not in wild type segregants. These results provided evidence that the locus controlling delta-15 desaturation was interrupted by T-DNA in mutant line 3707.

Isolation of Arabidopsis Genomic DNA
Containing the Gene Controlling Delta-15 Desaturation

In order to isolate the gene controlling delta-15 desaturation from wild-type Arabidopsis, a T-DNA-plant DNA "junction" fragment containing a T-DNA border integrated into the host plant DNA was isolated from Arabidopsis mutant 3707. For this, genomic DNA from the mutant plant was isolated and completely digested by either Bam HI or Sal I restriction enzymes. In each case, one of the resultant fragments was expected to contain the origin of replication and ampicillin-resistance gene of pBR322 as well as the left T-DNA-plant DNA junction fragment. Such fragments were rescued as plasmids by ligating the digested genomic DNA fragments at a dilute concentration to facilitate self-ligation and then using the ligated fragments to transform E. coli cells. Ampicillin-resistant E. coli transformants were isolated and screened by colony hybridization to fragments containing either the left or the right T-DNA border. Of the 192 colonies obtained from the plasmid rescue of Sal I digested genomic DNA, 31 hybridized with the left T-DNA border fragment, 4 hybridized to the right T-DNA border fragment, and none hybridized to both. Of the 85 colonies obtained from the plasmid rescue of Bam HI digested genomic DNA, 63

hybridized to the left border and none to the right border. Restriction analysis of seven rescued plasmids that were obtained from the Bam HI digestion and that hybridized to the left T-DNA border showed that they were indistinguishable and contained 1.4 kb of putative, flanking plant DNA. Restriction analysis of another rescued plasmid, pS1, that was obtained from the Sal I digestion and hybridized only to the left T-DNA border, showed that it contained 2.9 kb of putative, flanking plant DNA. This flanking DNA had a Bam HI site and a Hind III site 1.4 kb and 2.2 kb, respectively, away from the left T-DNA border, suggesting that the 1.4 kb putative plant DNA in Bam HI rescued plasmids was contained within the 2.9 kb putative plant DNA in the Sal I rescued plasmids. Southern blot analysis of wild type and mutant 3707 Arabidopsis genomic DNA using the radiolabeled 1.4 kb DNA fragment as the hybridization probe confirmed that this fragment contained plant DNA and that the T-DNA integration site was in a 2.8 kb Bam HI, a 5.2 kb Hind III, a 3.5 kb Sal I, a 5.5 kb Eco RI, and an approximately 9 kb Cla I fragment of wild type Arabidopsis DNA. Nucleotide sequencing of plasmid pS1 with a primer made to a left T-DNA border sequence revealed that pS1 was colinear with the sequence of the left T-DNA border (Yadav et al., Proc. Natl. Acad. Sci. USA (1982) 79:6322-6326) up to nucleotide position 65, which is in the T-DNA border repeats. Approximately 800 bp of additional sequence in pS1 beyond the T-DNA-plant DNA junction, that is, in the plant DNA adjoining the left T-DNA border, showed no significant homology to the T-DNA of pGV3850::pAK1003 and no significant open reading frame.

The nucleic acid fragment from wild-type Arabidopsis corresponding to the plant DNA flanking T-DNA in the line 3707 was isolated by screening a

lambda phage _Arabidopsis thaliana_ genomic library with the 1.4 kb plant DNA isolated from the rescued plasmids as a hybridization probe. Seven positively-hybridizing genomic clones were isolated that fell in one of five classes based on partial restriction mapping. While their average insert size was approximately 15 kb, taken together they spanned a total of approximately 40 kb of genomic DNA. A combination of restriction and Southern analyses revealed that the five clones overlapped the site of integration of the left border of the T-DNA and that there was no detectable rearrangement of plant DNA in the rescued plasmids as compared to that in the wild type genomic plant DNA. One of these lambda phage clones, designated 1111, was representative of the recovered clones and contained an approximately 20 kb genomic DNA insert which was more or less symmetrically arranged around the site of insertion of the left border of the T-DNA. This clone was deposited on November 27, 1991 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 75167.

Isolation of _Arabidopsis_ Delta-15
Desaturase cDNA

A 5.2 kb Hind III fragment containing wild-type genomic DNA, which hybridized to the 1.4 kb flanking plant DNA recovered from line 3707 and which was interrupted near its middle by the T-DNA insertion in line 3707, was isolated from lambda phage clone 41A1 and cloned into the Hind III site of the pBluescript SK vector (Stratagene) by standard cloning procedures described in Sambrook et·al., Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). The resultant plasmid was designated pF1. The isolated 5.2 kb Hind III fragment was also used as a radiolabeled hybridization probe to screen a

cDNA library made to poly A^+ mRNA from 3-day-old etiolated Arabidopsis thaliana (ecotype Columbia) seedling hypocotyls in a lambda ZAP II vector (Stratagene). Of the several positively-hybridizing plaques, four strongly-hybridizing ones were subjected to plaque purification. Sequences of the pBluescript (Stratagene) vector, including the cDNA inserts, from each of the purified phage stocks were excised in the presence of a helper phage. The resultant phagemids were used to infect E. coli cells which yielded double-stranded plasmids, pCF1, pCF2, pCF3, and pCF4. All four were shown to contain at least one approximately 1.3 to 1.4 kb Not I insert fragment (Not I/Eco RI adaptors were used in the preparation of the cDNA library) which hybridized to the same region of wild-type plant genomic DNA present in the isolated phage clones. This region, which was near the site of integration of the left T-DNA border in line 3707, was on the side of the T-DNA insertion opposite to that of the plant DNA flanking the left T-DNA border isolated previously via plasmid rescue. Partial sequence determination of the different cDNAs revealed common identity. Since multiple versions of only one type of cDNA were obtained from a cDNA library made from etiolated tissue which is expected to express delta-15 desaturation, and since these cDNAs hybridized to the genomic DNA that corresponds to the site of T-DNA integration in line 3707 which had a high linoleic acid/low linolenic acid phenotype, Applicants were lead to conclude that the T-DNA in line 3707 interrupted the normal expression of the gene encoding delta-15 desaturase. The complete nucleotide sequence of one cDNA, designated pCF3, was determined and is shown as SEQ ID NO:1. It reveals an open reading frame that encodes a 386 amino acid polypeptide. One of the sequencing primers made to the pCF3 insert was also used

to obtain 255 bp of sequence from pF1 that is shown as SEQ ID NO:3. Nucleotides 68 to 255 of the genomic DNA in pF1 (SEQ ID NO:3) are identical to nucl otides 1 to 188 of the cDNA (SEQ ID NO:1), which shows that they are colinear and that the cDNA is encoded for by the gene in the isolated genomic DNA. Nucleotides 113 to 115 in SEQ ID NO:3 are the initiation codon of the largest open reading frame corresponding to nucleotides 46-48 in SEQ ID NO:1. This is evident from the presence of in-frame termination codons at nucleotides 47 to 49 and nucleotides 56 to 58 and the absence of observable intron splice junctions in SEQ ID NO:3. The identification of the 386 amino acid polypeptide as a desaturase was confirmed by comparing its amino acid sequence with all the protein sequences found in Release 19.0 of the SWISSPROTEIN database using the FASTA algorithm of Pearson and Lipman (Proc. Natl. Acad. Sci. USA (1988) 85:2444-2448) and the BLAST program (Altschul et al., J. Mol. Biol. (1990) 215:403-410). The most homologous protein found in both searches was the desA fatty acid desaturase from the cyanobacterium Synechocystis PCC6803 (Wada, et al., Nature (1990) 347:200-203; Genbank ID:CSDESA; GenBank Accession No:X53508). The 386 amino acid peptide in SEQ ID NO:1 was also compared to the 351 amino acid sequence of desA by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453). Over their entire length, these proteins were 26% identical, the comparison imposing four major gaps in the desA protein sequence. While this overall homology is poor, homology in shorter stretches was better. For instance, in a stretch of 78 amino acids the Arabidopsis delta-15 desaturase (amino acids 78 to 155 in SEQ ID NO:1) and the desA protein (amino acids 67 to 144) showed 40% identity and 66% similarity.

Homology in yet shorter stretches was even greater as shown in Table 2.

TABLE 2

Peptide Length	AA positions in SEQ ID NO:1	AA positions in desA	Percent Identity
12	97-108	86-97	83
7	115-121	104-110	71
9	133-141	22-130	56
11	299-309	282-292	64

These high percent identities in short stretches of amino acids between the cyanobacterial desaturase polypeptide and SEQ ID NO:2 suggests significant relatedness between the two.

To analyse the developmental expression of the gene encoding mRNA coresponding to SEQ ID NO:1, the cDNA insert in plasmid pCF3 was used as a radiolabeled hybridization probe on mRNA samples from leaf, root, germinating seedling, and developing siliques from both wild type amd mutant 3707 Arabidopsis plants, essentially as described in Maniatis et al., Molecular Cloning, A Laboratory Manual (1982) Cold Spring Harbor Laboratory Press. The results indicated that while the mRNA corresponding to SEQ ID NO:1 is detected in all tissues from the mutant plant, its levels are lower than in wild-type tissues. This is consistent with the observation that the fatty acid mutation in line 3707 is leaky relative to the known Arabidopsis fad 3 mutant obtained via chemical mutagenesis. These results confirmed that the T-DNA in line 3707 had interrupted the normal expression of a fatty acid desaturase gene. Based on the fatty acid phenotype of homozygous mutant line 3707, Applicants concluded that the cDNA insert in pCF3 encoded the delta-15 desaturase. Further, Applicants concluded that it was the microsomal delta-15 desaturase, and not the chloroplastic delta-15

desaturase, since: a) the mutant phenotype was expressed strongly in the seed but express d poorly, if at all, in the leaf of line 3707, and b) the delta-15 desaturase polypeptide, by comparison to the desA polypeptide, did not have an N-terminal extension of a transit peptide expected for a nuclear-encoded chloroplast desaturase.

The identity of SEQ ID NO:2 as the *Arabidopsis* microsomal delta-15 desaturase was confirmed by its biological overexpression in plant tissues. For this, the 1.4 kB Not I fragment of plasmid pCF3 containing the delta-15 desaturase cDNA was placed in the sense orientation behind either the CaMV 35S promotor, to provide constituitive expression, or behind the promotor for the gene encoding soybean a' subunit of the β-conglycinin (7S) seed storage protein, to provide embryo-specific expression. The chimeric genes 35S promoter/sense SEQ ID NO:1/3' nopaline synthase and β-conglycinin/sense SEQ ID NO:1/3' phaseolin were then transformed into plant cells by *Agrobacterium tumefaciens*'s binary Ti plasmid vector system [Hoekema et al. (1983) Nature 303:179-180; Bevan (1984) Nucl. Acids Res. 12:8711-8720].

To confirm the identity of SEQ ID NO:1 and to test the biological effect of its overexpression in a heterologous plant species, the chimeric genes 35S promoter/sense SEQ ID NO:1/3' nopaline synthase was transformed into a binary vector, which was then transferred into *Agrobacterium tumefaciens* strain R1000, carrying the Ri plasmid pRiA4b from *Agrobacterium rhizogenes* [Moore et al. (1979) Plasmid 2:617-626]. Carrot (*Daucus carota* L.) cells were transformed by co-cultivation of carrot root disks with strain R1000 carrying the chimeric gene by the method of Petit et al. (1986) [Mol. Gen. Genet. 202:388-393]. Fatty acid

analyses of transgenic carrot "hairy" roots show that overexpression of Arabidopsis microsomal d lta-15 desaturase can result in over 10-fold increase in 18:3 at the expense of 18:2.

To complement the delta-15 desaturation mutation in the T-DNA mutant line 3707 and to test the biological effect of overexpression of SEQ ID NO:1 in seed, the embryo-specific promoter/SEQ ID NO:1/3' phaseolin chimeric gene was transformed into a binary vector, which was then transformed into the avirulent Agrobacterium strain LBA4404/pAL4404 [Hoekema et al. (1983) Nature 303:179-180]. Roots of line 3707 were transformed by the engineered Agrobacterium, transformed plants were selected and grown to give rise to seeds. Fatty acid analysis of the seeds from two plants showed that the one out of six seeds in each plant showed the mutant fatty acid phenotype, while the remaining seeds show more than 10-fold increase in 18:3 to ca. 55%. While the sample size is small, this segregation suggests Mendelian inheritance of the fatty acid phenotype. While most of the increase occurs at the expense of 18:2, some of it also occurs at the expense of 18:1. Thus, overexpression of this gene in oils crops, especially canola, which is a close relative of Arabidopsis, is also expected to result in the high levels of 18:3 that are found in specialty oil of linseed.

Comparisons of the sequence of the 386 amino acid polypeptide by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453) with those for the microsomal stearoyl-CoA (delta-9) desaturases from rat, mouse and yeast revealed 21%, 19%, and 17% identities, respectively. While the membrane-associated Arabidopsis delta-15 desaturase protein showed significant but limited homology to the desA protein, it showed no

significant homology to the soluble stearoyl-ACP (delta-9) desaturases from higher plants, including one from Arabidopsis.

Comparison of partial nucleotide sequences of plasmids pF1 and pS1 showed that the left T-DNA border:plant DNA junction is ca. 700 bp from the initiaton codon in SEQ ID NO:1. To determine the position of the other T-DNA:plant DNA junction with respect to the pF1 sequence, the T-DNA:plant DNA junction fragment was isolated. Genomic DNA from mutant line 3707, isolated as described previously, was partially digested by restriction enzyme Mbo I to give an average fragment size of ca. 15 kB. The fragment ends were partially-filled with dGTP and gATP by Klenow and cloned into Xho I half-sites of LambdaGEM®-11 (Promega Corporation) following the manufacturer's protocol. The phage library was titered and used essentially as described in Ausubel et al. [Current Protocols in Molecular Biology (1989) John Wiley & Sons]. The genomic phage library was screened with radiolabeled PCR product, ca. 0.6 kB, derived from 5' end of the gene in pF1. This product spans from 3 bp to the right of where the left-T-DNA border inserted to 15 bp to the left of nucleotide position 1 in SEQ ID NO:1. Southern blot analysis of DNA from one of the purified, positively-hybridizing phages following Eco RI restriction digestion and electrophoresis showed that a 4 kB Eco RI fragment hybridized to the 0.6 kB PCR product. The Eco RI fragment was subcloned and subject to sequence analyses. Comparison of the sequences derived from this fragment, pF1 and pS1 showed that the insertion of T-DNA resulted in a 56 bp deletion at the site of insertion and that the T-DNA interrupted the Arabidopsis gene 711 bp 5' to the initiaton codon in SEQ ID NO:1. Thus, the T-DNA inserts 5' to the open reading

frame, consistent with the leaky expresssion of the gene encoding SEQ ID NO:1 and the leaky fatty acid phenotype in mutant 3707. While the left T-DNA:plant DNA junction is precise, that is without any sequence rearrangement in either the left T-DNA border or the flanking plant DNA, the other T-DNA:plant DNA junction is complex and not fully characterized.

Plasmid pCF3 was deposited on December 3, 1991 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 68875.

Using _Arabidopsis_ Delta-15 Desaturase cDNA as a Hybridization Probe to Isolate cDNAs Encoding _Related Desaturases from Arabidopsis_

The 1.4 kb Not I insert fragment isolated from plasmid pCF3 was purified, radiolabeled, and used to screen approximately 80,000 clones from the cDNA library made to poly A^+ mRNA from 3-day-old etiolated _Arabidopsis thaliana_ as described above, except that lower stringency hybridizations (1 M NaCl, 50 mM Tris-HCl, pH 7.5, 1% SDS, 5% dextran sulfate, 0.1 mg/mL denatured salmon sperm DNA and 50°C) and washes (sequentially with 2X SSPE, 0.1% SDS at room temperature for 5 min and then again with fresh solution for 10 min, and finally with 0.5X SSPE, 0.1% SDS at 50°C for 5 min.) were used. Approximately 17 strongly-hybridizing and 17 weakly-hybridizing plaques were identified in the primary screen. Four of the weakly-hybridizing plaques were picked and subjected to one or two further rounds of screening with the radiolabeled probe as above until they were pure. To ensure that these were not delta-15 desaturase clones, they were further analyzed to determine whether they hybridized to an 18 bp oligomer specific to the 3' non-coding region of delta-15 desaturase cDNA (pCF3). After autoradiography of the

filters, one of the clones was found not to hybridize to this probe. This clone was picked, and a plasmid clone containing the cDNA insert was obtained as described above. Restriction analysis of this plasmid, designated pCM2, showed that it had an approximately 1.3 kb cDNA insert which lacked a 0.7 kb Nco I - Bgl II fragment characteristic of the _Arabidopsis_ delta-15 desaturase cDNA of pCF3. (This fragment corresponds to the DNA located between the Nco I site at nucleotides 474 to 479 and the Bgl II site at nucleotides 1164 to 1169 in SEQ ID NO:1). Partial nucleotide sequences of single strands from the 5' region and 3' region of pCM2 revealed that the cDNA insert was incomplete and that it encoded a polypeptide that is similar to, but distinct from, that encoded by the cDNA in pCF3. In order to isolate a full-length version of the cDNA in plasmid pCM2, the 1.3 kB Not I fragment from plasmid pCM2 containing the cDNA insert was isolated and used as a radiolabeled hybridization probe to rescreen the same _Arabidopsis_ cDNA library as above. Three strongly hybridizing plaques were purified and the plasmids excised as described previously. The three resultant plasmids were digested by Not I restriction enzyme and shown to contain cDNA inserts ranging in size between 1 kB and 1.5 kB. Complete nucleotide sequence determination of the cDNA insert in one of these plasmids, designated pACF2-2, is shown in SEQ ID NO:4. SEQ ID NO:4 shows the 5' to 3' nucleotide sequence of base pairs of the _Arabidopsis thaliana_ cDNA which encodes a fatty acid desaturase. Nucleotides 10-12 and nucleotides 1358 to 1350 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 10 to 1350). The open reading frame was confirmed by comparison of its deduced amino acid sequences with that of the related delta-15

fatty acid desaturase from soybean in this application. Nucleotides 1 to 9 and 1351 to 1525 are, respectively, the 5' and 3' untranslated nucleotides. The 446 amino acid protein sequence in SEQ ID NO:5 is that deduced from the open reading frame in SEQ ID NO:4 and has an estimated molecular weight of 51 kD. Alignment of SEQ ID NOS:2 and 5 shows an overall homology of approximately 80% and that the former has an approximately 55 amino acid long N-terminal extension, which is deduced to be a transit peptide found in nuclear-encoded plastid proteins.

To analyse the developmental expression of the gene corresponding to SEQ ID NO:4, this sequence was used as a radiolabeled hybridization probe on mRNA samples from leaf, root, germinating seedling, and developing siliques from both wild type and mutant line 3707 Arabidopsis plants, essentially as described in Maniatis et al. [Molecular Cloning, A Laboratory Manual (1982) Cold Spring Harbor Laboratory Press]. The results indicated that, in contrast to the constitutive expression of the gene encoding SEQ ID NO:1, the mRNA corresponding to SEQ ID NO:4 is abundant in green tissues, rare in roots and leaves, and is about three-fold more abundant in leaf than that of SEQ ID NO:1. The cDNA in plasmid pCM2 was also shown to hybridize polymorphically to genomic DNA from Arabidopsis thaliana (ecotype Wassileskija and marker line W100 ecotype Landesberg background) digested with Eco RI. It was used as a RFLP marker to map the genetic locus for the gene encoding this fatty acid desaturase in Arabidopsis. A single genetic locus was positioned corresponding to this desaturase cDNA. Its location was thus determined to be on chromosome 3 between the lambda AT228 and cosmid c3838 RFLP markers, "north" of the glabrous locus (Chang et al., Proc. Natl. Acad. Sci. USA (1988)

85:6856-6860; Nam et al., Plant Cell (1989) 1:699-705). This approximates the region to which Arabidopsis fatty acid desaturase fad 2, fad D, and fad B mutations map [Somerville et al., (1992) in press]. Unsuccessful efforts to clone the microsomal delta-12 fatty acid desaturase using cDNA inserts of pCF3 and pACF2-2 alongwith the above data led Applicants to conclude that the cDNA in pACF2-2 encodes a plastid delta-15 fatty acid desaturase that corresponds to the fad D locus. This conclusion will be confirmed by biological expression of the cDNA in pACF2-2.

Plasmid pCM2 was deposited on November 27, 1991 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 68852.

The 1.4 kb, 1.3 kB, and 1.5 kB Not I cDNA insert fragments isolated from plasmids pCF3, pCM2 and pACF2-2 were purified, radiolabeled, and used several times to screen at low stringency as described above two different cDNA libraries: one was made to poly A^+ mRNA from 3-day-old etiolated Arabidopsis thaliana ("etiolated" library) as described above and one made to polyA^+ mRNA from the above-ground parts of Arabidopsis thaliana plants, which varied in size from those that had just opened their primary leaves to plants which had bolted and were flowering [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735]. The cDNA inserts in the library were made into an Xho I site flanked by Eco RI sites in lambda Yes vector [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735] ("leaf" library). Several plaques from both libraries that hybridized weakly and in duplicate lifts to both SEQ ID NOS:1 and 4 were subjected to plaque purification. Phagemids were excised from the pure phages from "etiolated" library as described above. Plasmids were

excised from the purified phages of the "leaf" library by site-specific recombination using the cre-lox recombination system in E. coli strain BNN132 [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735]. In all cases, nucleotide sequencing of the cloned DNA revealed clones either identical to SEQ ID NOS:1 or 4 or unrecognizable sequences.

In another set of experiments ca. 400,000 phages in the "leaf" library was screened with SEQ ID NOS:1 and 4 at low stringency (26 C, 1 M Na+, 50% formamide) and high stringency (42 C, 1 M Na+, 50% formamide). Of the several positive signals on the primary plaque lifts, 11 showed high stringency hybridization to SEQ ID NO:1, 35 showed high stringency hybridization to SEQ ID NO:4, and 39 hybridized to both at low stringency only. Twenty seven plaques of the low stringency signals came through a secondary low-stringency screen, 17 of which were used to make DNA from excised plasmids. Of the 7 plasmid DNA were sequenced, 8 were unrecognizable sequences, 5 were identical to SEQ ID NO:1, 2 were identical to SEQ ID NO:2, and 2 were identical to one another and related but distinct to SEQ ID NOS:1 and 4. The novel desaturase sequence, designated pFad-x2, was also isolated from the "leaf" library independently by using as a hybridization probe a 0.6 kB PCR product derived by polymerase chain reaction on poly A+ RNA made from both canola seed as well as Arabidopsis leaves, as described elsewhere in this application, using degenerate oligomers made to conserved sequences between plant delta-15 desaturases and the cyanobacterial des A desaturase. The PCR-derived plasmid, designated pYacp7, was sequenced partially from both ends. Comparison of the sequences of pFad-x2 and pYacp7 revealed that the two independently cloned cDNAs contained an identical sequence that was related to the other delta-15

desaturases and that both were incomplete cDNAs. A partial composite sequence derived from both plasmids, pFadx-2 and pYacp7, is shown in SEQ ID NO:16 as a 5' to 3' nucleotide sequence of 472 bp. Nucleotides 2-4 and nucleotides 468 to 470 are, respectively, the first and the last codons in the open reading frame. This open reading frame is shown in SEQ ID NO:17. Comparison of SEQ ID NO:17 to the other delta-15 desaturase polypeptides disclosed in this application by the method of Needleman et al. [J. Mol. Biol. (1970) 48:443-453)] using gap weight and gap length weight values of 3.0 and 0.1, respectively. The overall identities are between 65% and 68% between SEQ ID NO:17 and the microsomal delta-15 desaturases from Arabidopsis, canola and soybean and the overall identities are between 77% and 87% between SEQ ID NO:17 and the plastid delta-15 desaturases from Arabidopsis, canola and soybean. In addition SEQ ID NO:17 has an N-terminal peptide extension compared to the microsomal delta-15 desaturases that shows homology of the transit peptide sequence in Arabidopsis plastid delta-15 desaturase. On the basis of these comparisons it is deduced that SEQ ID NO:16 encodes a plastid delta-15 desaturase. There is genetic data in Arabidopsis suggesting the presence of two loci for plastid delta-15 desaturase. The full-length version of SEQ ID NO:16 can be readily isolated by one skilled in the art. The biological effect of introducing SEQ ID NO:16 or its full-length version into plants will be used to confirm its identity.

Plasmid pYacp7 was deposited on 20 November 1992 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 69129.

Using *Arabidopsis* Delta-15 Desaturase cDNAs as Hybridization Probes to Isolate Delta-15 Desaturase cDNAs from Other Plant Species

For the purpose of cloning the *Brassica napus* seed cDNAs encoding delta-15 fatty acid desaturases, the cDNA inserts from pCF3 and pCM2 were isolated by polymerase chain reaction from the respective plasmids, radiolabeled, and used as hybridization probes to screen a lambda phage cDNA library made with poly A^+ mRNA from developing *Brassica napus* seeds 20-21 days after pollination. This cDNA library was screened several times at low stringency, using the *Arabidopsis* cDNA probes mentioned above. One of the *Brasssica napus* cDNAs obtained in the initial screens was used as probe in a subsequent high stringency screen.

Arabidopsis pCM2 insert was radiolabeled and used as probe to screen approximately 300,000 plaques under low stringency hybridization conditions. The filter hybridizations were performed in 50 mM Tris pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 ug denatured calf thymus DNA at 50°C overnight, and the posthybridization washes were carried out in 6X SSC, 0.5% SDS at room temperature for 15 min, then repeated with 2X SSC, 0.5% SDS at 45°C for 30 min, and then repeated twice with 0.2X SSC, 0.5% SDS at 50°C for 30 min. Five strongly-hybridizing phages were obtained. These were plaque purified and used to excise the phagemids as described in the manual of the pBluescriptII Phagemid Kit from Stratagene (Stratagene 1991 catalogue, item 212205). One of these, designated pBNSF3-2, contained a 1.3 kb insert. pBNSF3-f2 was sequenced completely on both strands and the nucleotide sequence is shown in SEQ ID NO:6. Plasmid pBNSF3-2 was deposited on 27 November 1991 with the American Type Culture Collection of

Rockville Maryland, USA under the provisions of the Budapest Treaty and bears the accession number 68854.

An additional low stringency screen using pCM2 probe provided eight strongly hybridizing phages. One of these, designated pBNSFd 8, contained a 0.4kb insert. pBNSFd-8 was sequenced completely on one strand, this nucleotide sequence showed significant divergence from the sequence SEQ ID NO:6 in the homologous region, which suggested that it corresponded to a novel Brassica napus seed desaturase different from that shown in SEQ ID NO:6. pBNSFd-8 insert was radiolabelled and used as hybridization probe in a high stringency screen of the Brassica napus seed cDNA library. The hybridization conditions were identical to those of the low stringency screen described above except for the temperature of the final two 30 min posthybridization washes in 0.2x SSC, 0.5% SDS was increased to 60°C. This screen resulted in three strongly hybridizing phages that were purified and excised. One of the excised plasmids pBNSFd-3 contained a 1.4kb insert that was sequenced completely on both strands. SEQ ID NO:8 shows the complete nucleotide sequence of pBNSFd-2.

Using Arabidopsis Delta-15 Desaturase cDNA as a Hybridization Probe to Isolate a Glycerolipid Desaturase cDNA from Soybean

A cDNA library was made to poly A^+ mRNA isolated from developing soybean seeds, and screened essentially as described above, except that filters were prehybridized in 25 mL of hybridization buffer consisting of 50mM Tris-HCl, pH 7.5, 1 M NaCl, 1% SDS, 5% dextran sulfate and 0.1 mg/mL denatured salmon sperm DNA (Sigma Chemical Co.) at 50°C for 2 h. Radiolabeled probe prepared from pCF3 as described above was added, and allowed to hybridize for 18 h at 50°C. The probes were washed twice at room temperature with 2X SSPE, 1%

SDS for five min followed by washing for 5 min at 50°C in 0.2X SSPE, 1% SDS. Autoradiography of the filt rs indicated that there was one strongly hybridizing plaque, and approximately five weakly hybridizing plaques. The more strongly hybridizing plaque was subjected to a second round of screening as before, except that the final wash was for 5 min at 60°C in 0.2X SSPE, 1% SDS. Numerous, strongly hybridizing plaques were observed, and one, well-isolated from other phage, was picked for further analysis.

Sequences of the pBluescript vector from the purified phage, including the cDNA insert, were excised in the presence of a helper phage and the resultant phagemid was used to infect E. coli XL-1 Blue cells. DNA from the plasmid, designated pXF1, was made by the alkaline lysis miniprep procedure described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press). The alkali-denatured double-stranded DNA from pXF1 was completely sequenced on both strands. The insert of pXF1 contained a stretch of 1783 nucleotides which contained an unknown open-reading frame and also contained a poly-A stretch of 16 nucleotides 3' to the open reading frame, from nucleotides 1767 to 1783, followed by an Eco RI restriction site. The 2184 bases that followed this Eco RI site contained a 1145 bp open reading frame which encoded a polypeptide of about 68% identity to, and colinear with, the Arabidopsis delta-15 desaturase polypeptide listed in SEQ ID No:2. The putative start methionine of the 1145 bp open-reading frame corresponded to the start methionine of the Arabidopsis microsomal delta-15 peptide and there were no amino acids corresponding to a plastid transit peptide 5' to this methionine. When the insert in pXF1 was digested with Eco RI four fragments were observed,

fragments of approximately 370 bp and 1400 bp fragments, derived from the first 1783 bp of the insert in pXF1, and fragments of approximately 600 bp and 1600 bp derived from the the other 2184 nucleotides of the insert in pXF1. Only the 600 bp and 1600 bp fragments hybridized with probe derived from pCF3 on Southern blots. It was deduced that pXF1 contained two different cDNA inserts separated by an Eco RI site and the second of these inserts was a 2184 bp cDNA encoding a soybean microsomal delta-15 desaturase. The complete nucleotide sequence of the 2184 bp soybean microsomal delta-15 cDNA contained in plasmid pXF1 is listed in SEQ ID No:10. Plasmid pXF1 was deposited on December 3, 1991 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 68874.

Using Soybean Microsomal Delta-15 Desaturase cDNA as a Hybridization Probe to Isolate cDNAs Encoding Related Desaturases from Soybean

A 1.0 kb fragment of DNA corresponding to part of the coding region of the soybean microsomal delta-15 desaturase cDNA contained in plasmid pXF1, was excised with the restriction enzyme Hha I and gel purified. The fragment was labeled with ^{32}P as described above and used to probe a soybean cDNA library as described above. Autoradiography of the filters indicated that there were eight hybridizing plaques and these were subjected to a second round of screening. Sequences of the pBluescript vector from all eight of the purified phages, including the cDNA inserts, were excised in the presence of a helper phage and the resultant phagemids were used to infect E. coli XL-1 Blue cells. DNA from the plasmids was made by the alkaline lysis miniprep procedure described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor

Laboratory Press). Restriction analysis showed they contained inserts ranging from 1.0 kb to 3.0 kb in size. One of these inserts, designated pSFD-118bwp, contained an insert of about 1700 bp. The alkali-denatured double-stranded DNA from pSFD-118bwp was completely sequenced on both strands, shown in SEQ ID NO:12. The insert of pSFD-118bwp contained a stretch of 1675 nucleotides which contained an open-reading frame encoding a polypeptide, shown in SEQ ID NO:13, of about 80% identity with, and colinear with, the Arabidopsis plastid delta-15 desaturase polypeptide listed in SEQ ID No:5. The open-reading frame also encoded amino acids corresponding to a plastid transit peptide at the 5' end of the open-reading frame. The transit peptide was colinear with, and shared some homology to, the transit peptide described for the Arabidopsis plastid delta-15 glycerolipid desaturase. The complete nucleotide sequence of the 1675 bp soybean plastid delta-15 glycerolipid desaturase cDNA is listed in SEQ ID No:12.

Comparison of the different delta-15 desaturase sequences disclosed in the application by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453) using gap weight and gap length weight values of 3.0 and 0.1, respectively, reveals the relatedness between them as shown in Table 3.

TABLE 3

Percent Identities Between Different Delta-15 Fatty Acid Desaturases at the Amino Acid Level

	aD	c3	cD	s3	sD
a3	66	93	66	68	67
aD	-	67	90	67	69
c3	-	-	68	68	68
cD	-	-	-	68	74

a3, ad, c3, cD, s3 and sD refer, respectively, to SEQ ID NO:2 (*Arabidopsis* microsomal delta-15 desaturase), SEQ ID NO:5 (*Arabidopsis* plastid delta-15 desaturase), SEQ ID NO:7 (canola microsomal delta-15 desaturase), SEQ ID NO:9 (canola plastid delta-15 desaturase), SEQ ID NO:11 (soybean microsomal delta-15 desaturase), and SEQ ID NO:13 (soybean plastid delta-15 desaturase). Based on these comparisons, the delta-15 desaturases, of both microsomal and plastid types, have overall identities of 65% or more at the amino acid levels, even when from different plant species.

Isolation of Nucleotide Sequences Encoding Homologous and Heterologous Glycerolipid Desaturases

Fragments of the instant invention may be used to isolate cDNAs and genes of homologous and heterologous glycerolipid desaturases from the same species as the fragment of the invention or from different species. Isolation of homologous genes using sequence-dependent protocols is well-known in the art. Southern blot analysis revealed that the *Arabidopsis* microsomal delta-15 desaturase cDNA (SEQ ID NO:1) hybridized to genomic DNA fragments of corn and soybean. In addition, Applicants have demonstrated that it can be used to isolate cDNAs encoding seed microsomal delta-15 desaturases from *Brassica napus* (SEQ ID NO:6) and soybean (SEQ ID NO:10). Thus, one can isolate cDNAs and

genes for homologous glycerolipid desaturases from the same or different higher plant species, especially from the oil-producing species.

More importantly, one can use the fragments of the invention to isolate cDNAs and genes for heterologous glycerolipid desaturases, including those found in plastids. Thus, Arabidopsis microsomal delta-15 desaturase cDNA (SEQ ID NO:1) was successfully used as a hybridization probe to isolate cDNAs encoding the related plastid delta-15 desaturases from Arabidopsis (SEQ ID NO:4) and Brassica napus (SEQ ID NO: 8), and the soybean microsomal delta-15 soybean (SEQ ID NO:10) was successfully used to isolate soybean cDNA encoding plastid delta-15 desaturase (SEQ ID NO:12).

In a particular embodiment of the present invention, regions of the nucleic acid fragments of the invention that are conserved between different desaturases may be used by one skilled in the art to design a mixture of degenerate oligomers for use in sequence-dependent protocols aimed at isolating nucleic acid fragments encoding other homologous or heterologous glycerolipid desaturase cDNA's or genes. For example, by comparing all desaturase polypeptides one can identify stretches of amino acids that are conserved between them, and then use the conserved amino acid sequence to design oligomers, both short degenerate or long ones, or "guessmers" as known by one skilled in the art (see Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). Such oligomers and "quessmers" may be used as hybridization probes as known to one skilled in the art.

For example, comparison of cyanobacterial desA and plant delta-15 desaturases revealed a particularly well conserved stretch of amino acids (amino acids 97-108 in

SEQ ID NO:1). SEQ ID NOS:20 and 21 represent two sets of 36-mers each 16-fold degenerate made to this r gion. End-labeled oligomers represented in SEQ ID NOS:20 and 21 were mixed and used as hybridzation probes to screen Arabidopsis cDNA libraries. Most of the positively-hybridizing plaques also hybridized to cDNAs encoding Arabidopsis microsomal and plastid delta-15 desaturases (SEQ ID NOS:1 and 4). However, the use of SEQ ID NOS:20 and 21 did not give consistent and reproducible results. A 135 base-long oligomer (SEQ ID NO:32) was also made as an antisense strand to a longer stretch of the same conserved region, amino acids 97 to 141 in SEQ ID NO:1 (FVLGHDCGHGSFSDIPLLNSVVGHILHSFILVPYHGWRISHRTHH). At positions of ambiguity, the design used either deoxyinosines or most frequently used codons based on the codon usage in Arabidopsis genes. When used as a hybridization probe, the 135-mer hybridized to all plaques that also hybridized to cDNAs encoding Arabidopsis microsomal and plastid delta-15 desaturases (SEQ ID NOS:1 and 4). In addition, it also hybridized to plaques that did not hybridize to SEQ ID NOS:1 and 4). The latter were purified and excised as described previously. Nucleotide sequencing of the cDNA inserts in the resultant plasmids revealed DNA sequences that did not show any relatedness to any desaturase.

For another example, in the polymerase chain reaction (Innis, et al., Eds, (1990) PCR Protocols: A Guide to Methods and Applications, Academic Press, San Diego), two short pieces of the present fragment of the invention can be used to amplify a longer glycerolipid desaturase DNA fragment from DNA or RNA. The polymerase chain reaction may also be performed on a library of cloned nucleotide sequences with one primer based on the fragment of the invention and the other on either the poly A^+ tail or a vector sequence. These oligomers may

be unique sequences or degenerate sequences derived from the nucleic acid fragments of the invention. The longer piece of homologous glycerolipid desaturase DNA generated by this method could then be used as a probe for isolating related glycerolipid desaturase genes or cDNAs from Arabidopsis or other species. The design of oligomers, including long oligomers using deoxyinosine, and "guessmers" for hybridization or for the polymerase chain reaction are known to one skilled in the art and discussed in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). Stretches of conserved amino acids between delta-15 desaturase and other desaturases, especially desA, allow for the design of such oligomers. For example, conserved stretches of amino acids between desA and delta-15 desaturase, discussed above, are useful in designing long oligomers for hybridization as well as shorter ones for use as primers in the polymerase chain reaction. In this regard, the conserved amino acid stretch of amino acids 97 to 108 of SEQ ID NO:2 is particularly useful. Other conserved regions in SEQ ID NO:2 useful for this purpose are amino acids 299 to 309, amino acids 115 to 121, and amino acids 133 to 141. Amino acid stretch 133 to 141 in SEQ ID NO:2 shows especially good homology to several desaturases. For example, in this stretch, amino acids 133, 137, 138, 140 and 141 are conserved in plant delta-15 desaturases, cyanobacterial desA, yeast and mammalian microsomal stearoyl-CoA desaturases. Comparison of cyanobacterial des A and plant delta-15 desaturases revealed two particularly well conserved stretch of amino acids (amino acids 97-108 and amino acids 299-311 in SEQ ID NO:1) that can be used for PCR. The following sets of PCR primers were made to these regions:

SEQ ID NO	Length	Fold Degeneracy	AA positions in SEQ ID NO:2	AA Sequence
20	36	16	97-108 (S)	FVLGHDCGHGSF
21	36	16	97-108 (S)	FVLGHDCGHGSF
28	36	16	97-108 (S)	FVLGHDCGHGSF
29	36	16	97-108 (S)	FVLGHDCGHGSF
22	18	72	100-105 (S)	GHDCGH
23	18	72	100-105 (S)	GHDCGH
24	18	72	299-304 (AS)	HDIGTH
25	18	72	299-304 (AS)	HDIGTH
26	23	416	304-309 (AS)	HVIHHL
27	23	416	304-309 (AS)	HVIHHL
30	38	64	299-311 (AS)	HDIGTHVIHHLFP
31	38	64	299-311 (AS)	HDIGTHVIHHLFP

In one experiment, PCRs were performed using SEQ ID NOS:22 and 23 as sense primers and either SEQ ID NOS:24 and 25 or SEQ ID NOS:26 and 27 as antisense primers on poly A+ RNA purified from both Arabidopsis leaf and canola developing seeds. All PCRs resulted in PCR products of the correct size (ca. 630 bp). The PCR products from Arabidopsis and canola were purified and used as radiolabeled hybridization probes to screen the Lambda Yes Arabidopsis cDNA library, as described above. This led to the isolation of a pure phage, which was excised to give plasmid pYacp7. The cDNA insert in pYacp7 was partially sequenced. It's sequence showed that it encoded an incomplete desaturase polypeptide that was identical to another cDNA (in plasmid pFadx-2) isolated by low-stringency hybridization as described previously. The composite sequence derived from the partial sequences from the cDNA inserts in pFadx-2 and pYacp7 is shown in SEQ ID NO:16 and the polypeptide encoded by it in SEQ ID NO:17. As discussed previously, SEQ ID NO:17 is a putative plastid delta-15 desaturase. This is further supported by Southern blot analysis

using radiolabeled cDNA inserts from either pCF3, pACF2-2, or pYacp7 on Arabidopsis genomic DNA digest d with one of several enzymes. It shows that the different inserts hybridize to different restriction fragments and that only the inserts from pACF2-2 and pYacp7 show some cross-hybridization.

In another PCR experiment, PCR was performed using ca. 80 pmoles each of SEQ ID NOS:28 and 29 as sense primers and ca. 94 pmoles each of SEQ ID NOS:30 and 31 as antisense primers on poly A+ RNA purified from Arabidopsis mutant line 3707. This was performed using GeneAmp® RNA PCR Kit (Perkin Elmer Cetus) following manufacturer's protocol and using the following program: a) 1 cycle of 2 min at 95°C, b) 35 cycles of 1 min at 95°C (denaturation), 1 min at 50°C (annealing) and 1 min at 65°C (extension), and c) 1 cycle of 7 min at 65°C. The resulting PCR product, of the correct size (ca. 630 bp), was purified, radiolabeled, and used as a hybridization probe on a Southern blot of Arabidopsis genomic DNA as described above. While it hybridized to restriction fragments that also hybridized to SEQ ID NOS:1 (Arabidopsis microsomal delta-15 desaturase), 4 (Arabidopsis plastid delta-15 desaturase), and 16 (Arabidopsis plastid delta-15 desaturase), it also hybridized to novel fragments that did not hybridze to previously cloned desaturase cDNAs. However, even after several attempts, the radiolabeled PCR product did not hybridize to any novel cDNA clone when used as a probe on different Arabidopsis cDNA libraries: in all cases it hybridzed only to plaques that also hybridized to the known desaturase cDNAs. Furthermore, the PCR product was subcloned into a plasmid vector and after screening about a 100 of these, none gave rise to a clone with a novel desaturase sequence.

The isolation of other glycerolipid d saturases will become easier as more examples of glycerolipid desaturases are isolated using the fragments of the invention. Knowing the conserved amino acid sequences from diverse desaturases will also allow one to identify more and better consensus sequences. Such sequences can be used to make hybridization probes or amplification primers which will further aid in the isolation of different glycerolipid desaturases, including those from non-plant sources such as fungi, algae, and even cyanobacteria, as well as other membrane-associated desaturases from other organisms.

The function of the diverse nucleotide fragments encoding glycerolipid desaturases that can be isolated using the present invention can be identified by transforming plants with the isolated desaturase sequences, linked in sense or antisense orientation to suitable regulatory sequences required for plant expression, and observing the fatty acid phenotype of the resulting transgenic plants. Preferred target plants for the transformation are the same as the source of the isolated nucleotide fragments when the goal is to obtain inhibition of the corresponding endogenous gene by antisense inhibition or cosuppression. Preferred target plants for use in expression or overexpression of the isolated nucleic acid fragments are plants with known mutations in desaturation reactions, such as the Arabidopsis desaturase mutants, mutant flax deficient in delta-15 desaturation, or mutant sunflower deficient in delta-12 desaturation. Alternatively, the function of the isolated nucleic acid fragments can be determined similarly via transformation of other organisms, such as yeast or cyanobacteria, with chimeric genes containing the nucleic acid fragment and suitable regulatory

sequences followed by analysis of fatty acid composition and/or enzyme activity.

Overexpression of the Glycerolipid Desaturase Enzymes in Transgenic Species

The nucleic acid fragment(s) of the instant invention encoding functional glycerolipid desaturase(s), with suitable regulatory sequences, can be used to overexpress the enzyme(s) in transgenic organisms. Such recombinant DNA constructs may include either the native glycerolipid desaturase gene or a chimeric glycerolipid desaturase gene isolated from the same or a different species as the host organism. For overexpression of glycerolipid desaturase(s), it is preferable that the introduced gene be from a different species to reduce the likelihood of cosuppression. For example, overexpression of delta-15 desaturase in soybean, rapeseed, or other oil-producing species to produce altered levels of polyunsaturated fatty acids may be achieved by expressing RNA from the entire cDNA found in pCF3. Similarly, the isolated nucleic acid fragments encoding glycerolipid desaturases from Arabidopsis, rapeseed, and soybean can also be used by one skilled in the art to obtain substantially homologous full-length cDNAs, if not already obtained, as well as the corresponding genes as fragments of the invention. These, in turn, may be used to overexpress the corresponding desaturases in plants. One skilled in the art can also isolate the coding sequence(s) from the fragment(s) of the invention by using and/or creating sites for restriction endonucleases, as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). For example, the fragment in SEQ ID NO:1 in plasmid pCF3 is flanked by Not I sites and can be isolated as a Not I fragment that can be introduced in

the sense orientation relative to suitable plant regulatory s quences. Alternatively, sites for Nco I (5'-CCATGG-3') or Sph I (5'-GCATGC-3') that allow precise removal of coding sequences starting with the initiating codon "ATG" may be engineered into the fragment(s) of the invention. For example, for utilizing the coding sequence of delta-15 desaturase from pCF3, an Sph I site can be engineered by substituting nucleotides at positions 44, 45, and 49 of SEQ ID NO:1 with G, C, and C, respectively.

Inhibition of Plant Target
Genes by Use of Antisense RNA

Antisense RNA has been used to inhibit plant target genes in a tissue-specific manner (see van der Krol et al., Biotechniques (1988) 6:958-976). Antisense inhibition has been shown using the entire cDNA sequence (Sheehy et al., Proc. Natl. Acad. Sci. USA (1988) 85:8805-8809) as well as a partial cDNA sequence (Cannon et al., Plant Molec. Biol. (1990) 15:39-47). There is also evidence that the 3' non-coding sequences (Ch'ng et al., Proc. Natl. Acad. Sci. USA (1989) 86:10006-10010) and fragments of 5' coding sequence, containing as few as 41 base-pairs of a 1.87 kb cDNA (Cannon et al., Plant Molec. Biol. (1990) 15:39-47), can play important roles in antisense inhibition.

The use of antisense inhibition of the glycerolipid desaturases may require isolation of the transcribed sequence for one or more target glycerolipid desaturase genes that are expressed in the target tissue of the target plant. The genes that are most highly expressed are the best targets for antisense inhibition. These genes may be identified by determining their levels of transcription by techniques, such as quantitative analysis of mRNA levels or nuclear run-off transcription, known to one skilled in the art.

For example, antisense inhibition of delta-15 desaturase in Brassica napus resulting in alter d levels of polyunsaturated fatty acids may be achieved by expressing antisense RNA from the entire or partial cDNA found in pBNSF3-2.

Inhibition of Plant Target Genes by Cosuppression

The phenomenon of cosuppression has also been used to inhibit plant target genes in a tissue-specific manner. Cosuppression of an endogenous gene using the entire cDNA sequence (Napoli et al., The Plant Cell (1990) 2:279-289; van der Krol et al., The Plant Cell (1990) 2:291-299) as well as a partial cDNA sequence (730 bp of a 1770 bp cDNA) (Smith et al., Mol. Gen. Genetics (1990) 224:477-481) are known.

The nucleic acid fragments of the instant invention encoding glycerolipid desaturases, or parts thereof, with suitable regulatory sequences, can be used to reduce the level of glycerolipid desaturases, thereby altering fatty acid composition, in transgenic plants which contain an endogenous gene substantially homologous to the introduced nucleic acid fragment. The experimental procedures necessary for this are similar to those described above for the overexpression of the glycerolipid desaturase nucleic acid fragments. For example, cosuppression of delta-15 desaturase in Brassica napus resulting in altered levels of polyunsaturated fatty acids may be achieved by expressing in the sense orientation the entire or partial seed delta-15 desaturase cDNA found in pBNSF3-2.

Selection of Hosts, Promoters and Enhancers

A preferred class of heterologous hosts for the expression of the nucleic acid fragments of the invention are eukaryotic hosts, particularly the cells of higher plants. Particularly preferred among the

higher plants are the oil-producing species, such as soybean (Glycine max), rapeseed (including Brassica napus, B. campestris), sunflower (Helianthus annus), cotton (Gossypium hirsutum), corn (Zea mays), cocoa (Theobroma cacao), safflower (Carthamus tinctorius), oil palm (Elaeis guineensis), coconut palm (Cocos nucifera), flax (Linum usitatissimum), and peanut (Arachis hypogaea).

Expression in plants will use regulatory sequences functional in such plants. The expression of foreign genes in plants is well-established (De Blaere et al., Meth. Enzymol. (1987) 153:277-291). The source of the promoter chosen to drive the expression of the fragments of the invention is not critical provided it has sufficient transcriptional activity to accomplish the invention by increasing or decreasing, respectively, the level of translatable mRNA for the glycerolipid desaturases in the desired host tissue. Preferred promoters include (a) strong constitutive plant promoters, such as those directing the 19S and 35S transcripts in cauliflower mosaic virus (Odell et al., Nature (1985) 313:810-812; Hull et al., Virology (1987) 86:482-493), and (b) tissue- or developmentally-specific promoters. Examples of tissue-specific promoters are the light-inducible promoter of the small subunit of ribulose 1,5-bis-phosphate carboxylase (if expression is desired in photosynthetic tissues), the maize zein protein promoter (Matzke et al., EMBO J. (1984) 3:1525-1532), and the chlorophyll a/B binding protein promoter (Lampa et al., Nature (1986) 316:750-752).

Particularly preferred promoters are those that allow seed-specific expression. This may be especially useful since seeds are the primary source of vegetable oils and also since seed-specific expression will avoid any potential deleterious effect in non-seed tissues.

Examples of s ed-specific promoters include, but are not limited to, the promoters of seed storage prot ins, which can represent up to 90% of total seed protein in many plants. The seed storage proteins are strictly regulated, being expressed almost exclusively in seeds in a highly tissue-specific and stage-specific manner (Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221; Goldberg et al., Cell (1989) 56:149-160). Moreover, different seed storage proteins may be expressed at different stages of seed development.

Expression of seed-specific genes has been studied in great detail (See reviews by Goldberg et al., Cell (1989) 56:149-160 and Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221). There are currently numerous examples of seed-specific expression of seed storage protein genes in transgenic dicotyledonous plants. These include genes from dicotyledonous plants for bean b-phaseolin (Sengupta-Gopalan et al., Proc. Natl. Acad. Sci. USA (1985) 82:3320-3324; Hoffman et al., Plant Mol. Biol. (1988) 11:717-729), bean lectin (Voelker et al., EMBO J. (1987) 6:3571-3577), soybean lectin (Okamuro et al., Proc. Natl. Acad. Sci. USA (1986) 83:8240-8244), soybean Kunitz trypsin inhibitor (Perez-Grau et al., Plant Cell (1989) 1:095-1109), soybean b-conglycinin (Beachy et al., EMBO J. (1985) 4:3047-3053; pea vicilin (Higgins et al., Plant Mol. Biol. (1988) 11:683-695), pea convicilin (Newbigin et al., Planta (1990) 180:461-470), pea legumin (Shirsat et al., Mol. Gen. Genetics (1989) 215:326-331); rapeseed napin (Radke et al., Theor. Appl. Genet. (1988) 75:685-694) as well as genes from monocotyledonous plants such as for maize 15 kD zein (Hoffman et al., EMBO J. (1987) 6:3213-3221), maize 18 kD oleosin (Lee at al., Proc. Natl. Acad. Sci. USA (1991) 888:6181-6185), barley b-hordein (Marris et al., Plant Mol. Biol. (1988)

10:359-366) and wheat glutenin (Colot et al., EMBO J. (1987) 6:3559-3564). Moreover, promoters of seed-specific genes operably linked to heterologous coding sequences in chimeric gene constructs also maintain their temporal and spatial expression pattern in transgenic plants. Such examples include use of Arabidopsis thaliana 2S seed storage protein gene promoter to express enkephalin peptides in Arabidopsis and B. napus seeds (Vandekerckhove et al., Bio/Technology (1989) 7:929-932), bean lectin and bean b-phaseolin promoters to express luciferase (Riggs et al., Plant Sci. (1989) 63:47-57), and wheat glutenin promoters to express chloramphenicol acetyl transferase (Colot et al., EMBO J. (1987) 6:3559-3564).

Of particular use in the expression of the nucleic acid fragment of the invention will be the heterologous promoters from several soybean seed storage protein genes such as those for the Kunitz trypsin inhibitor (Jofuku et al., Plant Cell (1989) 1:1079-1093; glycinin (Nielson et al., Plant Cell (1989) 1:313-328), and b-conglycinin (Harada et al., Plant Cell (1989) 1:415-425). Promoters of genes for a- and b-subunits of soybean β-conglycinin storage protein will be particularly useful in expressing the mRNA or the antisense RNA in the cotyledons at mid- to late-stages of seed development (Beachy et al., EMBO J. (1985) 4:3047-3053) in transgenic plants. This is because there is very little position effect on their expression in transgenic seeds, and the two promoters show different temporal regulation. The promoter for the a-subunit gene is expressed a few days before that for the b-subunit gene. This is important for transforming rapeseed where oil biosynthesis begins about a week before seed storage protein synthesis (Murphy et al., J. Plant Physiol. (1989) 135:63-69).

Also of particular use will be promoters of genes expressed during early embryogenesis and oil biosynthesis. The native regulatory sequences, including the native promoters, of the glycerolipid desaturase genes expressing the nucleic acid fragments of the invention can be used following their isolation by those skilled in the art. Heterologous promoters from other genes involved in seed oil biosynthesis, such as those for B. napus isocitrate lyase and malate synthase (Comai et al., Plant Cell (1989) 1:293-300), delta-9 desaturase from safflower (Thompson et al. Proc. Natl. Acad. Sci. USA (1991) 88:2578-2582) and castor (Shanklin et al., Proc. Natl. Acad. Sci. USA (1991) 88:2510-2514), acyl carrier protein (ACP) from Arabidopsis (Post-Beittenmiller et al., Nucl. Acids Res. (1989) 17:1777), B. napus (Safford et al., Eur. J. Biochem. (1988) 174:287-295),and B. campestris (Rose et al., Nucl. Acids Res. (1987) 15:7197), b-ketoacyl-ACP synthetase from barley (Siggaard-Andersen et al., Proc. Natl. Acad. Sci. USA (1991) 88:4114-4118), and oleosin from Zea mays (Lee et al., Proc. Natl. Acad. Sci. USA (1991) 88:6181-6185), soybean (Genbank Accession No: X60773) and B. napus (Lee et al., Plant Physiol. (1991) 96:1395-1397) will be of use. If the sequence of the corresponding genes is not disclosed or their promoter region is not identified, one skilled in the art can use the published sequence to isolate the corresponding gene and a fragment thereof containing the promoter. The partial protein sequences for the relatively-abundant enoyl-ACP reductase and acetyl-CoA carboxylase are also published (Slabas et al., Biochim. Biophys. Acta (1987) 877:271-280; Cottingham et al., Biochim. Biophys. Acta (1988) 954:201-207) and one skilled in the art can use these sequences to isolate the corresponding seed genes with their promoters. Similarly, the fragments of the

present invention encoding glycerolipid desaturases can be used to obtain promoter regions of the corresponding genes for use in expressing chimeric genes.

Attaining the proper level of expression of the nucleic acid fragments of the invention may require the use of different chimeric genes utilizing different promoters. Such chimeric genes can be transferred into host plants either together in a single expression vector or sequentially using more than one vector.

It is envisioned that the introduction of enhancers or enhancer-like elements into the promoter regions of either the native or chimeric nucleic acid fragments of the invention will result in increased expression to accomplish the invention. This would include viral enhancers such as that found in the 35S promoter (Odell et al., Plant Mol. Biol. (1988) 10:263-272), enhancers from the opine genes (Fromm et al., Plant Cell (1989) 1:977-984), or enhancers from any other source that result in increased transcription when placed into a promoter operably linked to the nucleic acid fragment of the invention.

Of particular importance is the DNA sequence element isolated from the gene for the a-subunit of b-conglycinin that can confer 40-fold seed-specific enhancement to a constitutive promoter (Chen et al., Dev. Genet. (1989) 10:112-122). One skilled in the art can readily isolate this element and insert it within the promoter region of any gene in order to obtain seed-specific enhanced expression with the promoter in transgenic plants. Insertion of such an element in any seed-specific gene that is expressed at different times than the b-conglycinin gene will result in expression in transgenic plants for a longer period during seed development.

The invention can also be accomplished by a variety of other methods to obtain the desired end. In one form, the invention is based on modifying plants to produce increased levels of glycerolipid desaturases by virtue of introducing more than one copy of the foreign gene containing the nucleic acid fragments of the invention. In some cases, the desired level of polyunsaturated fatty acids may require introduction of foreign genes for more than one kind of glycerolipid desaturase.

Any 3' non-coding region capable of providing a polyadenylation signal and other regulatory sequences that may be required for the proper expression of the nucleic acid fragments of the invention can be used to accomplish the invention. This would include 3' ends of the native glycerolipid desaturase(s), viral genes such as from the 35S or the 19S cauliflower mosaic virus transcripts, from the opine synthesis genes, ribulose 1,5-bisphosphate carboxylase, or chlorophyll a/b binding protein. There are numerous examples in the art that teach the usefulness of different 3' non-coding regions.

Transformation Methods

Various methods of transforming cells of higher plants according to the present invention are available to those skilled in the art (see EPO Pub. 0 295 959 A2 and 0 318 341 A1). Such methods include those based on transformation vectors utilizing the Ti and Ri plasmids of *Agrobacterium spp*. It is particularly preferred to use the binary type of these vectors. Ti-derived vectors transform a wide variety of higher plants, including monocotyledonous and dicotyledonous plants (Sukhapinda et al., Plant Mol. Biol. (1987) 8:209-216; Potrykus, Mol. Gen. Genet. (1985) 199:183). Other transformation methods are available to those skilled in the art, such as direct uptake of foreign DNA constructs

(see EPO Pub. 0 295 959 A2), techniques of electroporation (Fromm et al., Nature (1986) (London) 319:791) or high-velocity ballistic bombardment with metal particles coated with the nucleic acid constructs (Kline et al., Nature (1987) (London) 327:70). Once transformed, the cells can be regenerated by those skilled in the art.

Of particular relevance are the recently described methods to transform foreign genes into commercially important crops, such as rapeseed (De Block et al., Plant Physiol. (1989) 91:694-701), sunflower (Everett et al., Bio/Technology (1987) 5:1201), and soybean (Christou et al., Proc. Natl. Acad. Sci USA (1989) 86:7500-7504.

Application to RFLP Technology

The use of restriction fragment length polymorphism (RFLP) markers in plant breeding has been well-documented in the art (Tanksley et al., Bio/Technology (1989) 7:257-264). The nucleic acid fragments of the invention can be used as RFLP markers for traits linked to expression of glycerolipid desaturases. These traits will include altered levels of unsaturated fatty acids. The nucleic acid fragment of the invention can also be used to isolate the glycerolipid desaturase gene from variant (including mutant) plants with altered levels of unsaturated fatty acids. Sequencing of these genes will reveal nucleotide differences from the normal gene that cause the variation. Short oligonucleotides designed around these differences may be used as hybridization probes to follow the variation in polyunsaturates. Oligonucleotides based on differences that are linked to the variation may be used as molecular markers in breeding these variant oil traits.

EXAMPLES

The present invention is further defined in the following Examples, in which all parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be understood that these Examples, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. All publications, including patents and non-patent literature, referred to in this specification are expressly incorporated by reference herein.

EXAMPLE 1

ISOLATION OF GENOMIC DNA FLANKING THE T-DNA SITE OF INSERTION IN ARABIDOPSIS THALIANA MUTANT LINE 3707

Identification of an *Arabidopsis thaliana* T-DNA Mutant with Low Linolenic Acid Content

A population of *Arabidopsis thaliana* (geographic race Wassilewskija) transformants containing the T-DNA of *Agrobacterium tumefaciens* was generated by seed transformation as described by Feldmann et al., (Mol. Gen. Genetics (1987) 208:1-9). In this population the transformants contain DNA sequences encoding the pBR322 bacterial vector, nopaline synthase, neomycin phosphotransferase (NPTII, confers kanamycin resistance), and b-lactamase (confers ampicillin resistance) within the T-DNA border sequences. The integration of the T-DNA into different areas of the chromosomes of individual transformants may cause a disruption of plant gene function at or near the site of insertion, and phenotypes associated with this loss of

gene function can be analyz d by screening the population for the phenotype.

T3 seed was generated from the wild type seed treated with Agrobacterium tumefaciens by two rounds of self-fertilization as described by Feldmann et al., (Science (1989) 243:1351-1354). These progeny were segregating for the T-DNA insertion, and thus for any mutation resulting from the insertion. Approximately 100 seeds of each of 6000 lines were combined and the fatty acid content of each of the 6000 pooled samples was determined by gas chromatography of the fatty acyl methyl esters essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H_2SO_4 in methanol was used as the methylation reagent and samples were heated for 1.5 h at 80°C to effect the methanolysis of the seed triglycerides. A line designated "3707" produced seeds that gave an altered fatty acid profile compared to that of the total population. T3 plants were grown from individual T3 seeds produced by line 3707 and self-fertilized to produce T4 seeds on individual plants that were either homozygous wild type, homozygous mutant, or heterozygous for the mutation. The percent fatty acid compositions of a representative subsample of the entire population, of the pooled 3707 T3 seeds, and of a homozygous T4 mutant segregant are shown in Table 4.

TABLE 4

Fatty Acid Methyl Ester	T3 Pools from lines 3501-4000 average and (std. deviation)	3707 T3 Pool	3707 Homozygous T4 Segregant
palmitic	7.4 (0.37)	7.0	6.4
stearic	3.0 (0.22)	2.9	3.0
oleic	17.0 (1.5)	17.7	15.9
linoleic	29.3 (0.78)	35.0	42.4
linolenic	16.1 (1.1)	10.2	3.1
eicosenoic	20.2 (0.73)	20.5	23.6

The phenotype of the segregating T3 pool of line 3707 (high linoleic acid, low linolenic acid) was intermediate between that of the population subsample and the homozygous T4 mutant seeds suggesting that line 3707 harbored a mutation at a locus which controls the conversion of linoleic to linolenic acid in the seed. Still, it was not apparent whether the mutant phenotype in line 3707 was the result of a T-DNA insertion. Therefore, Applicants checked a segregating T4 population to determine whether the mutant fatty acid phenotype cosegregated with the nopaline synthase activity and kanamycin resistance encoded by the T-DNA insert. A total of 263 T4 plants were grown and assayed for the presence of nopaline in leaf extracts (Errampalli et al., The Plant Cell (1991) 3:149-157). In addition, T5 seeds were collected from each of the T4 plants and samples of 10-50 seeds were taken to determine the seed fatty acid composition and to determine their ability to germinate in the presence of kanamycin (Feldmann, et al., (1989) Science 243:1351-1354). The 263 plants fell into 3 classes as in Table 5.

TABLE 5

Number of Individuals	Phenotype
63	T4 plants: little or no nopaline present; T5 seeds: wild type fatty acid composition, all kanamycin sensitive
134	T4 plants: nopaline present; T5 seeds: heterozygous fatty acid composition similar to 3707 T3 pool, segregating for kanamycin resistance
64	T4 plants: nopaline present; T5 seeds homozygous mutant fatty acid composition, all kanamycin resistant

The cosegregation of the fatty acid phenotype with the phenotypes conferred by T-DNA sequences in an approximately 1:2:1 pattern provided strong evidence that the mutation in line 3707 was the result of a T-DNA insertion. Further experiments were then conducted with the intent of using probes containing T-DNA sequences to clone the T-DNA insert and flanking genomic DNA from line 3707.

Preparation of Genomic DNA from Homozygous 3707 Plants

Seeds from a homozygous line derived from *Arabidopsis thaliana* (geographic race Wassilewskija (WS)) line 3707 were surface sterilized for 5 min at room temperature in a solution of 5.25% sodium hypochlorite (w/v)/0.15% Tween 20 (v/v), then washed several times in sterile distilled water, with a final rinse in 50% ethanol. Immediately following the ethanol wash, the seeds were transferred to sterile filter paper to dry. One to three seeds were then transferred to 250-mL flasks containing 50 mL of sterile Gamborgs B5 media (Gibco, 500-1153EA), pH 6.0. Cultures were incubated at 22°C, 70 $\mu E \cdot /m^{-2} \cdot sec^{-1}$ of continuous light for approximately three weeks, after which time the root tissue was harvested, made into 10 g aliquots (wet weight), lyophilized, and stored at -20°C.

Using a variation of the procedure of Shure et al., (Cell (1983) 35:225-233) genomic DNA was isolated from the root tissue. Two aliquots of lyophilized tissue were ground to a fine powder using a mortar and pestle. The ground tissue was added to a flask containing 85 mL of lysis buffer (7 M urea, 0.35 M NaCl, 0.05 M Tris-HCl, pH 8.0, 0.02 M EDTA, 1% Sarkosyl, 5% phenol) and mixed gently with a glass rod to obtain a homogeneous suspension. To this suspension an equal volume of phenol:chloroform:isoamyl alcohol (25:24:1) (equilibrated with 10 mM Tris, pH 8, 1 mM EDTA) was added. After the addition of 8.5 mL of 10% SDS the mixture was swirled on a rotating platform for 15 min at room temperature. After centrifugation at 2000xg for 15 min, the upper aqueous phase was removed to a new tube and extracted two more times, as above, but without the addition of SDS. To the final aqueous phase was added 1/20th the volume of 3 M potassium acetate, pH 5.5 and two times the volume of ice cold 100% ethanol. Precipitation of the DNA was facilitated by incubation at -20°C for one hour followed by centrifugation at 12,000xg for 10 min. The resulting pellet was resuspended in 3 mL of 10 mM Tris, pH 8, 1 mM EDTA to which was added 0.95 g of cesium chloride (CsCl) and 21.4 µL of 10 mg/mL ethidium bromide (EtBr) per mL of solution. The DNA was then purified by centrifugation to equilibrium in a CsCl/EtBr density gradient for 16 h at 15°C, 265,000xg. After removal from the gradient, the DNA was extracted with isopropanol saturated with TE buffer (10 mM Tris, pH 8; 1 mM EDTA) and CsCl to remove EtBr and then dialyzed overnight at 4°C against 10 mM Tris, pH 8, 1 mM EDTA to remove CsCl. The DNA was removed from dialysis and the concentration was determined using the Hoechst fluorometric assay in which an aliquot of DNA is added to 3 mL of 1.5×10^{-6} M bis-

benzimide (Hoechst 33258, Siga) in 1X SSC (0.15 M NaCl, 0.015 M sodium citrate), pH 7.0, incubated at room temperature for 5 min, and read on a fluorometer at excitation 360, emission 450, against a known set of DNA standards.

Plasmid Rescue and Analysis

Five micrograms of genomic DNA from the homozygous 3707 mutant, prepared as described above, was digested with 20 units of either Bam HI or Sal I restriction enzyme (Bethesda Research Laboratory) in a 50 µL reaction volume according to the manufacturer's specifications. After digestion the DNA was extracted with buffer-saturated phenol (Bethesda Research Laboratory) followed by precipitation in ethanol. The resulting pellet was resuspended in a final volume of 10 µL of 10 mM Tris, pH 8, and the concentration of the DNA was determined using the Hoechst fluorometric assay as above.

To facilitate circularization, as opposed to end-to-end joining, a dilute ligation reaction was set up containing 250 ng of Bam HI or Sal I digested genomic DNA, 3 Weiss units of T4 DNA ligase (Promega), 50 µL of 10X ligase buffer (30 mM Tris-HCl, pH 7.8, 100 mM $MgCl_2$, 100 mM DTT, 5 mM ATP) and 5 µL of 100 mM ATP in a 500 µL reaction volume. The reaction was incubated for 16 h at 16°C, heated for 10 min at 70°C, and extracted once with buffer saturated phenol (Bethesda Research Laboratory). The DNA was then precipitated with the addition of two volumes of 100% ethanol and 1/10th volume of 7.5 M ammonium acetate. The resulting pellet was resuspended in a final volume of 10 µL of 10 mM Tris, pH 8, and the concentration of the DNA was determined using the Hoechst fluorometric assay as above.

Competent DH10B cells (Bethesda Research Laboratory) were transfected with 50 ng of ligated DNA

at a concentration of 10 ng of DNA per 100 µL of cells according to the manufacturer's specifications. Transformants from Sal I or Bam HI digests were selected on LB plates (10 g Bacto-tryptone, 5 g Bacto-yeast extract, 5 g NaCl, 15 g agar per liter, pH 7.4) containing 100 µg/mL ampicillin or 25 µg/mL kanamycin sulfate, respectively. Ampicillin-resistant (Amp^r; ampicillin sensitivity, Amp^s) Sal I tranformants were screened for the presence of the kanamycin resistance (Kan^r; kanamycin sensitivity, Kan^s) gene by picking primary tranformants and stabbing them first to LB plates containing 100 µg/mL ampicillin then to LB plates containing 25 µg/mL kanamycin. After overnight incubation at 37°C the plates were scored for Amp^r/Kan^s colonies. Kanamycin-resistant Bam HI transformants were screened for the presence of the ampicillin resistance gene by picking primary transformants and stabbing them first to LB plates containing 25 µg/mL kanamycin and then to LB plates containing 100 µg/mL ampicillin. After overnight incubation at 37°C the plates were scored for Kan^r/Amp^r colonies.

Cultures were made of 192 Amp^r/Kan^s Sal I transformants and 85 Kan^r/Amp^r Bam HI transformants directly into deep-well microtiter plates containing 200 µL of LB broth (10 g Bacto-tryptone, 5 g Bacto-yeast extract, 5 g NaCl per liter) with 100 µg/mL ampicillin. Using the Schleicher and Schuell Minifold I apparatus and Nytran membranes, dot blots were set up, in duplicate, using the following conditions: 50 µL of culture was diluted into 150 µL of 5X SSC, the culture was lysed and the DNA denatured by the addition of 150 µL of 0.5 M NaOH, 1.5 M NaCl solution for 3 min at room temperature, the filter was removed from the apparatus and neutralized in 0.5 M Tris, pH 8, 1.5 M NaCl, the DNA was then UV cross-linked to the filters

using the Stratagene Stratalinker, and the filters were heated for 2 h at 80°C and stored at room temperature.

To determine whether T-DNA was contained within any of the rescued plasmids, the dot blots were probed with portions of the right and left borders of T-DNA. The right border probe consisted of a 2.2 kb Hind III-Dra I fragment of DNA obtained from plasmid H23pKC7 (composed of the 3.2 kb Hind III 23 fragment from Ti plasmid pTiC58 (Lemmers et al., J. Mol. Biol. (1989) 144;353-376) cloned into plasmid vector pKC7 (Maniatis et al., Molecular Cloning, A Laboratory Manual (1982) Cold Spring Harbor Laboratory Press)), and the left border probe consisted of a 2.9 kb Hind III-Eco RI fragment obtained from plasmid H10pKC7 (composed of the 6.5 kb Hind III 10 fragment from Ti plasmid pTiC58 (Lemmers et al., J. Mol. Biol. (1989) 144:353-376) cloned into plasmid vector pKC7 (Maniatis et al., Molecular Cloning, A Laboratory Manual (1982) Cold Spring Harbor Laboratory Press)) using standard digestion, electrophoresis, and electroelution conditions as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed (1989) Cold Spring Harbor Laboratory Press). Final DNA purification was obtained by passage of the eluted DNA over an Elutip-D column (Schleicher and Schuell) using the manufacturer's specifications. Concentration of the DNA was determined using the Hoechst fluorometric assay as above. Approximately 100 ng of each probe was labeled with a[^{32}P]dCTP using a Random Priming Kit from Bethesda Research Laboratories under conditions recommended by the manufacturer. Labeled probe was separated from unincorporated a[^{32}P]dCTP by passing the reaction through a Sephadex G-25 spun column under standard conditions as described in Sambrook et al., (Molecular

Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press).

The filters were pre-hybridized in 150 mL of buffer consisting of 6X SSC, 10X Denhardt's solution, 1% SDS, and 100 µg/mL denatured calf thymus DNA for 16 h at 42°C. The denatured, purified, labeled probe was added to the pre-hybridized filters following transfer of the filters to 50 mL of hybridization buffer consisting of 6X SSC, 1% SDS, 10% dextran sulfate, and 50 µg/mL denatured calf thymus DNA. Following incubation of the filters in the presence of the probe for 16 h at 65°C, the filters were washed twice in 150 mL of 6X SSC, 0.5% SDS, twice in 1X SSC, 1% SDS and once in 0.1X SSC, 1% SDS, all at 65°C. The washed filters were subjected to autoradiography on Kodak XAR-2 film at 80°C overnight.

Of the 85 Bam HI candidates, 63 hybridized with the left border probe and none hybridized with the right border probe. Of the 192 Sal I candidates, 31 hybridized with the left border probe, 4 hybridized with the right border probe, and none hybridized with both probes. Twelve of the Bam HI candidates, 7 positive and 5 negative for the presence of the left border of T-DNA, were further analyzed by restriction digests.

DNA from the Bam HI candidates was made by the alkaline lysis miniprep procedure of Birmbiom et al., (Nuc. Acid Res. (1979) 7:1513-1523), as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). The plasmid DNA was digested with Eco RI restriction enzyme (Bethesda Research Laboratories) in accordance with the manufacturer's specifications and electrophoresed through a 0.8% agarose gel in 1X TBE buffer (0.089 M Tris-borate, 0.089 M boric acid, 0.002 M EDTA). All of the Bam HI candidates which hybridized with the left border probe of T-DNA had the same Eco RI

restriction pattern, which indicated the presence of 14.2 kb of T-DNA and 1.4 kb of putative plant genomic DNA in these clones.

DNA from Sal I candidates was isolated, restriction-analyzed using Eco RI, Bam HI and Sal I enzymes, and electrophoresed through a 0.8% agarose gel, as above. All of the Sal I candidates which hybridized with the left border probe of T-DNA included 2.9 kb of putative plant DNA. Contained within this 2.9 kb fragment was a 1.4 kb Bam HI-Eco RI fragment as seen with the Bam HI rescued plasmids, suggesting that the 1.4 kb fragment was a subset of the 2.9 kb fragment and that it was adjacent to the left border of the T-DNA at its site of insertion into the plant genome. Sequence analysis of one Sal I candidate (pS1) using a primer homologous to the left border sequence of T-DNA, revealed that the sequence of pS1 was colinear with the sequence of the T-DNA left border (Yadav et al., Proc. Natl. Acad. Sci. USA (1982) 79:6322-6326) up to nucleotide 65, followed by non-T-DNA (putative plant) sequences.

Southern Analysis with Putative Plant
<u>DNA from Rescued Plasmids</u>

DNA from the seven Bam HI candidates which hybridized with the left border of the T-DNA was pooled and a portion was digested with Eco RI and Bam HI restriction endonucleases and electrophetically separated on a 0.8% agarose gel in 1X TBE buffer. After excising a 1.4 kb Eco RI-Bam HI fragment from the agarose gel, the 1.4 kb fragment was purified by use of a Gene Clean Kit from Bio 101. Fifty nanograms of the resulting DNA fragment was labeled with a[^{32}P]dCTP using a Random Priming Kit (Bethesda Research Laboratory) under conditions recommended by the manufacturer.

Three micrograms of total genomic DNA from homozygous wild-type *Arabidopsis* and homozygous 3707 mutant *Arabidopsis* plants was digested to completion with one of the following restriction enzymes: Sal I, Hind III, Eco RI, Cla I, and Bam HI under conditions suggested by the manufacturer. The digested DNA was subjected to electrophoresis and Southern transfer to Hybond-N membranes (Amersham) as described in Sambrook et al. (Molecular Cloning, A Laboratory Approach, 2nd. ed. (1989) Cold Spring Harbor Laboratory Press). After Southern transfer, the membranes were exposed to UV light using the Stratalinker (Stratagene) as per the manufacturer's instructions, air dried, and heated at 68°C for 2 h.

The filters were prehybridized in 1 M NaCl, 50 mM Tris-Cl, pH 7.5, 1% sodium dodecyl sulfate, 5% dextran sulfate, 100 µg/mL of denatured salmon sperm DNA at 65°C overnight. Fifty nanograms of the radiolabeled 1.4 kb Eco RI-Bam HI plant DNA fragment prepared above was added to the prehybridization solution containing the Southern blot and further incubated at 65°C overnight. The filter was washed for 10 min twice in 200 mL 2X SSPE, 0.1% sodium dodecyl sulfate at 65°C and for 10 min in 200 mL 0.5% SSPE, 0.1% sodium dodecyl sulfate at 65°C. Hybridizing fragments were detected by autoradiography. The analysis confirmed that the probe fragment contained plant DNA and that the T-DNA integration site was in a 2.8 kb Bam HI, a 5.2 kb Hind III, a 3.5 kb Sal I, a 5.5 kb Eco RI, and an approximately 9 kb Cla I fragment of wild type *Arabidopsis* DNA.

Isolation of Lambda Clones Containing the Wild Type *Arabidopsis Delta-15 Desaturase Gene*

The 1.4 kb Eco RI-Bam HI fragment (see above) was used as a probe to screen a lGem-11 library made from

genomic DNA isolated from wildtype Arabidopsis thaliana plants, geographic race WS. To construct the library, genomic DNA was partially digested with Sau3A enzyme, and size-fractionated over a salt gradient as described in Sambrook et al. (Molecular Cloning, A Laboratory Approach, 2nd ed. (1989) Cold Spring Harbor Laboratory Press). The size-fractionated DNA was then cloned into Bam HI-digested lGem-11 phage DNA (Promega) following the protocol outlined by the manufacturer. About 25,000 plaque-forming units of phage each were plated on five 150 mm petri plates containing a lawn of KW251 cells on NZY agar media (5 g NaCl, 2 g $MgSO_4 \cdot 7H_2O$, 5 g yeast extract, 10 g NZ Amine (casein hydrolysate from ICN Pharmaceuticals), 15 g agar per liter; pH 7.5). The plaques were adsorbed onto nylon membranes (Colony/Plaque Screen, New England Nuclear), in duplicate, and prepared according to the manufacturer's instructions with the addition of a 2 h incubation at 80°C after air drying the filters. The filters were prehybridized at 65°C in hybridization buffer (1% BSA, 0.5 M NaP_i, pH 7.2, (NaH_2PO_4 and Na_2HPO_4), 10 mM EDTA, and 7% SDS) for 4 h, after which time they were transferred to fresh buffer containing the denatured radiolabeled probe (see above) and incubated overnight at 65°C. The filters were rinsed twice with 0.1X SSC, 1% SDS at 65°C for 30 min each and subjected to autoradiography on Kodak XA-R film at 80°C overnight. Seven positively-hybridizing plaques were subjected to plaque purification as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press).

Small scale (5 mL) liquid lysates from each of the 7 clones were prepared and titered on KW251 bacteria as described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed (1989), Cold Spring Harbor

Laboratory Press). Phage DNA was isolated using a variation of the method of Chisholm (Biotechniques (1989) 7:21-23) in which the initial lysate was made according to Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed (1989), Cold Spring Harbor Laboratory Press) the concentration of DNase I and RNase I (Sigma) was reduced by half, and the PEG precipitation step was increased to 16 h. Based on restriction analysis using Hind III, Sal I and Xho I enzymes, the original 7 positive phage fell into 5 different classes. While the average insert size was approximately 15 kb, taken together the clones spanned a 40 kb region of genomic DNA. Through restriction mapping using 4 different enzymes (Hind III, Bam HI, Kpn I, and Sal I) singly, and in pair-wise combinations, accompanied by Southern analysis with the 1.4 kb Eco RI-Bam HI probe (as above) and other probes obtained from the 1 clones themselves, a partial map was obtained in which all 5 clones (11111, 141A1, 14211, 14311 and 14411) were found to share an approximately 3 kb region of homology near the site of T-DNA insertion. Via restriction and Southern analysis, Applicants ascertained that a 5.2 kb Hind III fragment present in clones 1111, 41A1, and 4411 also spanned the site of the T-DNA insertion. This fragment was excised from lambda clone 41A1, inserted into the Hind III site of the pBluescript vector (Stratagene), and the resulting plasmid, designated pF1, was prepared and isolated using standard protocols. This Hind III fragment was subsequently used to probe an <u>Arabidopsis</u> cDNA library (see below).

EXAMPLE 2

CLONING OF *ARABIDOPSIS THALIANA* DELTA-15 DESATURASE cDNA USING GENOMIC DNA FLANKING THE T-DNA SITE OF INSERTION IN *ARABIDOPSIS THALIANA* MUTANT LINE 3707 AS A HYBRIDIZATION PROBE

The 5.2 kb Hind III fragment from plasmid pF1 was purified by electrophoresis in agarose after digestion of the plasmid with Hind III and radiolabeled with ^{32}P as described above. For the preparation of an *Arabidopsis* cDNA library, polyadenylated mRNA was prepared from 3 day-old, etiolated *Arabidopsis* (ecotype Columbia) seedling hypocotyls using standard protocols (Sambrook, et al., Molecular Cloning: A Laboratory Manual, 2nd Ed. (1989) Cold Spring Harbor Laboratory Press). Five micrograms of this mRNA were used as template with an oligo d(T) primer, and Moloney Murine Leukemia Virus reverse transcriptase (Pharmacia) was used to catalyze first strand cDNA synthesis. Second-strand cDNA was made according to Gubler et al., (Gene (1983) 25:263-272) except that DNA ligase was omitted. After the second strand synthesis, the ends of the cDNA were made blunt by reaction with the Klenow fragment of DNA polymerase and ligated to Eco RI/Not I adaptors (Pharmacia). The cDNA's were purified by spun-column chromatography using Sephacryl S-300 and size-fractionated on a 1% low melting point agarose gel. Size-selected cDNAs (1-3 kb) were removed from the gel using agarase (New England Biolabs) and purified by phenol:chloroform extraction and ethanol precipitation. One hundred nanograms of the cDNA was co-precipitated with 1 µg of 1 ZAP II (Stratagene) Eco RI-digested, dephosphorylated arms. The DNAs were ligated in a volume of 4 µL overnight, and the ligation mix was packaged *in vitro* using the Gigapack II Gold packaging extract (Stratagene).

Approximately 80,000 phage were screen d for positively hybridizing plaques using the radiolab led 5.2 kb Hind III fragment as a probe essentially as described above and in Sambrook et al., (Molecular Cloning: A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press). Replica filters of the phage plaques were soaked in 1 M NaCl, 50 mM Tris-HCl, pH 7.5, 1% SDS, 5% dextran sulfate, 0.1 mg/mL denatured salmon sperm DNA during the pre-hybridization step (8 hr at 65°C) and then probe was added and the hybridization proceeded over 16 hr at the same temperature. Filters were washed sequentially with 2X SSPE, 0.1% SDS at room temperature for 5 min and then again with fresh solution for 10 min, and finally with 0.5X SSPE, 0.1% SDS at 65°C for 5 min. Approximately 20 positively hybridizing plaques were identified in the primary screen. Four of these were picked and subjected to two further rounds of screening and purification. From the tertiary screen, four pure phage plaques were isolated. Plasmid clones containing the cDNA inserts were obtained through the use of a helper phage according to the *in vivo* excision protocol provided by Stratagene. Double-stranded DNA was prepared using the alkaline lysis method as previously described, and the resulting plasmids were size-analyzed by electrophoresis in agarose gels. The largest one of these, designated pCF3, contained an approximately 1.4 kb insert which was sequenced using Sequenase T7 DNA polymerase (US Biochemical Corp.) and the manufacturer's instructions, beginning with primers homologous to vector sequences that flank the cDNA insert and continuing serially with primers designed from the newly acquired sequences as the sequencing experiment progressed. The sequence of this insert is shown in SEQ ID NO:1.

EXAMPLE 3

CLONING OF AN ARABIDOPSIS CDNA ENCODING A PLASTID DELTA-15 FATTY ACID DESATURASE

A related fatty acid desaturase was cloned in a similar fashion, except that the probe used was not derived from a PCR reaction on pCF3, but rather was the actual 1.4 kb Not I fragment isolated from pCF3 which was purified and radiolabeled as described above.

Approximately 80,000 phage from the *Arabidopsis* etiolated hypocotyl cDNA library described above were plated out and screened essentially as before, except as indicated below. The filters were soaked in 1 M NaCl, 50 mM Tris-HCl, pH 7.5, 1% SDS, 5% dextran sulfate, 0.1 mg/mL denatured salmon sperm DNA during the pre-hybridization step (8 hr at 50°C). Then probe was added and the hybridization proceeded over 16 hr at the same temperature. Filters were washed sequentially with 2X SSPE, 0.1% SDS at room temperature for 5 min and then again with fresh solution for 10 min, and finally with 0.5X SSPE, 0.1% SDS at 50°C for 5 min. Approximately 17 strongly hybridizing and 17 weakly hybridizing plaques were identified in the primary screen. Four of the weakly hybridizing plaques were picked and subjected to one to two further rounds of screening with the radiolabeled probe as above until they were pure. To ensure that these were not delta-15 desaturase clones, they were further analyzed to determine whether they hybridized to a delta-15 desaturase 3' end-specific probe. The probe used was an 18 bp oligonucleotide which is complementary in sequence (i.e., antisense) to nucleotides 1229 - 1246 of SEQ ID NO:1. The probe was radiolabeled with gamma-^{32}P ATP using T4 polynucleotide kinase and hybridized to filters containing DNA from the isolated clones in 6X SSC, 5X Denhardt's, 0.1 mg/mL denatured salmon sperm DNA, 1 mM EDTA, 1% SDS at 44°C

overnight. The filters were washed twice in 6X SSC, 0.1% SDS for 5 min at room temperature, then in 6X SSC, 0.1% SDS at 44°C for 3-5 min. After autoradiography of the filters, one of the clones failed to show hybridization to this probe. This clone was picked, and a plasmid clone containing the cDNA insert was obtained through the use of a helper phage according to the in vivo excision protocol provided by Stratagene. Double-stranded DNA was prepared using the alkaline lysis method as previously described, and the resulting plasmid was size-analyzed by electrophoresis in agarose gels following either Not I digestion or digestion with both Nco I and Bgl II. The results were consistent with the presence in this plasmid, designated pCM2, of an approximately 1.3 kb cDNA insert which lacked a 0.7 kb Nco I - Bgl II fragment characteristic of the Arabidopsis delta-15 desaturase cDNA of pCF3. (This fragment corresponds to the DNA located between the Nco I site at nucleotides 474-479 and the Bgl II site at nucleotides 1164-1169 in SEQ ID NO:1). The complete nucleotide sequence of pCM2 is shown in SEQ ID NO:4.

EXAMPLE 4

CLONING OF PLANT FATTY ACID DESATURASE cDNAs FROM OTHER SPECIES BY HYBRIDIZATION TECHNIQUES

An approximately 1.4 kb fragment containing the Arabidopsis delta-15 desaturase coding sequence of SEQ ID NO:1 was obtained from plasmid pCF3 through the use of the polymerase chain reaction (PCR). Primers (M13(-20) and T7-17mer primers, 1991 Stratagene Catalogue numbers 300303 and 300302, respectively) flanking the pCF3 insert were used in the PCR which was carried out essentially as described in the instructions provided by the vendor in the Perkin-Elmer/Cetus PCR kit. This fragment was digested with Not I to remove vector sequences, purified by agarose gel electro-

phoresis, and radiolabeled with ^{32}P as previously described.

EXAMPLE 5

CLONING OF BRASSICA NAPUS SEED cDNAs ENCODING DELTA-15 FATTY ACID DESATURASES

A cDNA library from developing Brassica napus seeds was constructed using the polyadenylated mRNA fraction contained in a polysomal RNA preparation from developing Brassica napus seeds. Polysomal RNA was isolated following the procedure of Kamalay et al., (Cell (1980) 19:935-946) from seeds 20-21 days after pollination. The polyadenylated mRNA fraction was obtained by affinity chromatography on oligo-dT cellulose (Aviv et al., Proc. Natl. Acad. Sci. USA (1972) 69:1408-1411). Four micrograms of polyadenylated mRNA were reverse transcribed and used to construct a cDNA library in lambda phage (Uni-ZAP™ XR vector) using the protocol described in the ZAP-cDNA™ Synthesis Kit (1991 Stratagene Catalog, Item # 200400).

For the purpose of cloning the Brassica napus seed cDNAs encoding delta-15 fatty acid desaturases, the Brassica napus seed cDNA library was screened several times using the inserts from the Arabidopsis cDNAs pCF3 and pCM2 as radiolabelled hybridization probes. One of the Brasssica napus cDNAs obtained in these screens was used as hybridization probe in a subsequent screen.

For each screening experiment approximately 300,000 phages were screened under low stringency hybridization conditions. The filter hybridizations were carried out in 50 mM Tris pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 ug denatured calf thymus DNA at 50°C overnight and the p[ost hybridization washes were performed in 6X SSC, 0.5% SDS at room temperature for 15 min, then repeated with 2X SSC, 0.5% SDS at 45°C for 30 min, and then

repeated twic with 0.2X SSC, 0.5% SDS at 50°C for 30 min.

Using the Arabidopsis cDNA insert of pCM2 as a probe in a low stringency screen five strongly hybridizing phages were identified. These phages were purified and excised according to the protocols described in the ZAP-cDNA™ Synthesis Kit and pBluescript II Phagemid Kit (1991 Stratagene Catalog, Item # 200400 and 212205). One of these, designated pBNSF3-f2, contained a 1.3 kb insert. pBNSF3-f2 insert was sequenced completely on both strands. pBNSF3-f2 nucleotide sequence is shown in SEQ ID NO:6. A comparison of this sequence with that of the Arabidopsis thaliana delta-15 desaturase clone (SEQ ID NO:1) confirmed that pBNSF3-f2 is a Brassica napus cDNA that encodes a seed microsomal delta-15 desaturase.

An additional low stringency screen of the Brassica napus seed cDNA library using the cDNA insert in pCM2 as a probe identified eight strongly-hybridizing phages. These phages were plaque purified and used to excise the phagemids as described above. One of these, designated pBNSFd-8, contained a 0.3kb insert. pBNSFd-8 was sequenced completely on one strand, this sequence had significant divergence from the sequence of pBNSF3-f2. The cDNA insert in pBNSFd-8 was used as a hybridization probe in a high stringency screen of the Brassica napus seed cDNA library. The filter hybridizations were carried out in 50 mM Tris pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 ug denatured calf thymus DNA overnight at 50°C and post hybridization washes were in 6X SSC, 0.5% SDS at room temperature for 15 min, then with 2X SSC, 0.5% SDS at 45°C for 30 min, and then twice with 0.2X SSC, 0.5% SDS at 60°C for 30 min. The high stringency screen resulted in three strongly hybridizing phages that were purified and excised as above. One of the

excised plasmids pBNSFd-3 contained a 1.4kb insert that was sequenced completely on both strands. SEQ ID NO:8 shows the nucleotide sequence of pBNSFd-3. A comparison of this sequence with that of the Arabidopsis thaliana delta-15 desaturase clone (SEQ ID NO:4) confirmed that pBNSFd-3 is a Brassica napus cDNA that encodes a seed plastid delta-15 desaturase.

Cloning of a Soybean Seed cDNA Encoding a Microsomal Delta-15 Glycerolipid Desaturase

A cDNA library was made as follows: Soybean embryos (ca. 50 mg fresh weight each) were removed from the pods and frozen in liquid nitrogen. The frozen embryos were ground to a fine powder in the presence of liquid nitrogen and then extracted by Polytron homogenization and fractionated to enrich for total RNA by the method of Chirgwin et al. (Biochemistry (1979) 18:5294-5299). The nucleic acid fraction was enriched for poly A^+RNA by passing total RNA through an oligo-dT cellulose column and eluting the poly A^+RNA with salt as described by Goodman et al. (Meth. Enzymol. (1979) 68:75-90). cDNA was synthesized from the purified poly A^+RNA using cDNA Synthesis System (Bethesda Research Laboratory) and the manufacturer's instructions. The resultant double-stranded DNA was methylated by Eco RI DNA methylase (Promega) prior to filling-in its ends with T4 DNA polymerase (Bethesda Research Laboratory) and blunt-end ligation to phosphorylated Eco RI linkers using T4 DNA ligase (Pharmacia). The double-stranded DNA was digested with Eco RI enzyme, separated from excess linkers by passage through a gel filtration column (Sepharose CL-4B), and ligated to lambda ZAP vector (Stratagene) according to manufacturer's instructions. Ligated DNA was packaged into phage using the Gigapack packaging extract (Stratagene) according to manufacturer's instructions. The resultant cDNA library

was amplified as per Stratagene's instructions and stored at -80°C.

Following the instructions in the Lambda ZAP Cloning Kit Manual (Stratagene), the cDNA phage library was used to infect E. coli BB4 cells and approximately 80,000 plaque forming units were plated onto 150 mm diameter petri plates. Duplicate lifts of the plates were made onto nitrocellulose filters (Schleicher & Schuell). The filters were prehybridized in 25 mL of hybridization buffer consisting of 50mM Tris-HCl, pH 7.5, 1 M NaCl, 1% SDS, 5% dextran sulfate and 0.1 mg/mL denatured salmon sperm DNA (Sigma Chemical Co.) at 50°C for 2 h. Radiolabeled probe prepared from pCF3 as described above was added, and allowed to hybridize for 18 h at 50°C. The probes were washed twice at room temperature with 2X SSPE, 1% SDS for five minutes followed by washing for 5 min at 50°C in 0.2X SSPE, 1% SDS. Autoradiography of the filters indicated that there was one strongly hybridizing plaque, and approximately five weakly hybridizing plaques. The more strongly hybridizing plaque was subjected to a second round of screening as before, excepting that the final wash was for 5 min at 60°C in 0.2X SSPE, 1% SDS. Numerous, strongly hybridizing plaques were observed, and one, well-isolated from other phage, was picked for further analysis.

Following the Lambda ZAP Cloning Kit Instruction Manual (Stratagene), sequences of the pBluescript vector, including the cDNA inserts, from the purified phage was excised in the présence of a helper phage and the resultant phagemid was used to infect E. coli XL-1 Blue cells. DNA from the plasmid, designated pXF1, was made by the alkaline lysis miniprep procedure described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory

Press). The alkali-denatured double-stranded DNA from pXF1 was completely sequenced on both strands. The insert of pXF1 contained a stretch of 1783 nucleotides which contained an unknown open-reading frame and also contained a poly-A stretch of 16 nucleotides 3' to the open reading frame, from nucleotides 1767 to 1783, followed by an Eco RI restriction site. The 2184 bases that followed this Eco RI site contained a 1145 bp open reading frame which encoded a polypeptide of about 68% identity to, and colinear with, the Arabidopsis delta-15 desaturase polypeptide listed in SEQ ID No:2. The putative start methionine of the 1145 bp open-reading frame corresponded to the start methionine of the Arabidopsis microsomal delta-15 peptide and there were no amino acids corresponding to a plastid transit peptide 5' to this methionine. When the insert in pXF1 was digested with Eco RI four fragments were observed, fragments of approximately 370 bp and 1400 bp fragments, derived from the first 1783 bp of the insert in pXF1, and fragments of approximately 600 bp and 1600 bp derived from the the other 2184 nucleotides of the insert in pXF1. Only the 600 bp and 1600 bp fragments hybridized with probe derived from pCF3 on Southern blots. It was deduced that pXF1 contained two different cDNA inserts separated by an Eco RI site and the second of these inserts was a 2184 bp cDNA encoding a soybean microsomal delta-15 desaturase. The complete nucleotide sequence of the 2184 bp soybean microsomal delta-15 cDNA contained in plasmid pXF1 is listed in SEQ ID No:10.

Cloning of a Soybean Seed cDNA Encoding a Plastid Delta-15 Glycerolipid Desaturase Using Soybean Microsomal Delta-15 Desaturase cDNA as an Hybridization Probe

A 1.0 kb fragment of the coding region of the soybean microsomal delta-15 desaturase cDNA contained in

plasmid pXF1 was excised by digestion with the restricti n enzyme Hha I. This 1.0 Kb fragment was purified by agarose gel electrophoresis and radiolabeled with 32P as previously described. The radiolabeled fragment was used to screen 100,000 plaque-forming units of the the soybean cDNA library as described above. Autoradiography of the filters indicated that there were eight hybridizing plaques and these were subjected to a second round of screening. Sequences of the pBluescript vector from all eight of the purified phages, including the cDNA inserts, were excised in the presence of a helper phage and the resultant phagemids were used to infect E. coli XL-1 Blue cells. DNA from the plasmids was made by the alkaline lysis miniprep procedure described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press). Restriction analysis showed they contained inserts ranging from 1.0 kb to 3.0 kb in size. One of these inserts, designated pSFD-118bwp, contained an insert of about 1700 bp. The alkali-denatured double-stranded DNA from pSFD-118bwp was completely sequenced on both strands. The insert of pSFD-118bwp contained a stretch of 1675 nucleotides which contained an open-reading frame encoding a polypeptide of about 80% identity with, and colinear with, the Arabidopsis plastid delta-15 desaturase polypeptide listed in SEQ ID No:5. The open-reading frame also encoded amino acids corresponding to a plastid transit peptide at the 5' end of the open-reading frame. The transit peptide was colinear with, and shared some homology to, the transit peptide described for the Arabidopsis plastid delta-15 glycerolipid desaturase. Based on the homology to Arabidopsis plastid delta-15 glycerolipid desaturase and because of the presence of a plastid transit peptide, the cDNA contained in plasmid pSFD-118bwp was deduced to

be a soybean plastid delta-15 glycerolipid desaturase. The complete nucleotide sequ nce of the 1675 bp soybean plastid delta-15 glycerolipid desaturase cDNA is listed in SEQ ID NO:12.

EXAMPLE 6

CLONING OF cDNA SEQUENCES ENCODING FATTY ACID DESATURASES BY POLYMERASE CHAIN REACTION

Analysis of the deduced protein sequences of the different higher plant glycerolipid desaturases described in this invention reveals to those skilled in the art regions of the amino acid sequences that have been conserved among higher plants and between higher plants and cyanobacterial des A. These short stretches of amino acids can be used to design oligomers as primers for polymerase chain reactions. Two amino acid sequences that are highly conserved between the des A and plant delta-15 desaturases polypeptides are amino acid sequences 97-108 and 299-311 (SEQ ID NO:2). Polymerase chain reactions (PCRs) were performed using GeneAmp® RNA PCR Kit (Perkin Elmer Cetus) following manufacturer's protocols. In one PCR experiment, SEQ ID NOS:22 and 23 were used as sense primers and either SEQ ID NOS:24 and 25 or SEQ ID NOS:26 and 27 as antisense primers on poly A+ RNA purified from both *Arabidopsis* leaf and canola developing seeds. For this, ca. 100 ng of polyA+ RNA was isolated as described previously and reverse-transcribed using the kit using random hexamers. Then the cDNA was used in PCR using 64 pmoles each of SEQ ID NOS:22 and 23 as sense primers and either a mixture of 64 pmoles of SEQ ID NO:24 and 78 pmoles of SEQ ID NO:25 or a mixture 35 pmoles of SEQ ID NO:26 and 50 pmoles of SEQ ID NO:27 by the following program: a) 1 cycle of 2 min at 95°C and 15 C at 50°C, b) 30 cycles of 3 min at 65°C (extension), 1 min 20 sec at 95°C (denaturation), 2 min at 50°C (annealing), and c) 1

cycle of 7 min at 65°C. PCR products were analyzed by gel electrophoresis. All PCRs resulted in PCR products of the correct size (ca. 630 bp). The PCR products from Arabidopsis and canola were purified and used as radiolabeled hybridization probes to screen the Lambda Yes Arabidopsis cDNA library at low stringency, as described above. This led to the isolation of a pure phage, which was excised to give plasmid pYacp7. The cDNA insert in pYacp7 was partially sequenced. Its sequence showed that it encoded an incomplete desaturase polypeptide that was identical to another cDNA (in plasmid pFadx-2) isolated by low-stringency hybridization as described previously. The composite sequence derived from the partial sequences from the cDNA inserts in pFadx-2 and pYacp7 is shown in SEQ ID NO:16 and the polypeptide encoded by it in SEQ ID NO:17. As discussed previously, SEQ ID NO:17 is a putative plastid delta-15 desaturase. A full-length version of pYacp7 can be readily isolated using it has a hybridization probe.

Two additional conserved regions correspond to aminoacid residues 130 to 137 and 249 and 256 of SEQ ID NO:7 (Brassica napus glycerolipid desaturase delta-15). Degenerate oligomers were designed to these regions with additional nucleotides containing a restriction site for Bam H1 were added to the 5' ends of each oligonucleotide to facilitate subcloning of the PCR products. The nucleotide sequences of these oligonucleotides named F2-3 and F2-3c are shown in SEQ ID NO:18 and SEQ ID NO:19 respectively.

Mixtures of degenerate oligonucleotides F2-3 and F2-3c were used to amplify, isolate and clone glycerolipid desaturase sequences represented in corn seed mRNA population, essentially as described in the GeneAmp RNA PCR Kit purchased from Perkin Elmer Cetus and in Innis,

et al., Eds, (1990) PCR Protocols: A Guide to Methods and Applications, Academic Press, San Diego.

Corn seed RNA was obtained from developing corn seeds 15-20 days after pollination by the method of Chirgwin et al., (1979) Biochemistry 18:5294. Corn seed polyadenylated mRNA was isolated by affinity chromatography on oligo-dT cellulose (Aviv et al., Proc. Natl. Acad. Sci. USA (1972) 69:1408-1411). 20-50ng of A+mRNA were used in reverse transcription reactions with oligo-dT and random hexamers primers using the reaction buffer and conditions recomended by Perkin Elmer Cetus. The resulting cDNA was then used as template for the amplification of corn seed glycerolipid sequences using the set of degenerate primers in SEQ ID NO: 18 and 19. Reaction conditions were as described by Perkin Elmer Cetus, the amplification protocol consisted of a sequence of 95°C/1 min, 55°C/1 min, 72°C/2 min for 30-50 cycles. The resulting polymerase reaction products were phenol-chloroform extracted, digested with Bam HI and separated from unincorporated primers by gel filtration chromatopgraphy on Linker 6 spin columns (Pharmacia Inc.). The resulting PCR products were cloned into pBluescript SK at the Bam H1 site, and transformed into E. coli DH5 competent cells. Restriction analysis of plasmid DNA from the transformed colonies obtained revealed a colony, PCR-20, that contained an insert of about 0.5 kB in size at the pBluescript SK BamH1 site. The PCR-20 insert was completely sequenced on both strands. The nucleotide sequence of PCR20 insert is shown in SEQ ID NO:14 and the translated amino acid sequence is shown in SEQ ID NO:15. This aminoacid sequence shows an overall identity of 61.9% to the aminoacid sequence of Brassica napus microsomal delta-15 deaturase shown in SEQ ID NO:7. This result identifies the PCR20 insert as a polymerase reaction product of a

corn seed delta-15 desaturase cDNA. PCR20 insert may be used as a probe to readily isolate full length corn seed delta-15 desaturase cDNAs or as such to antisense or cosuppress corn seed glycerolipid delta-15 desaturase gene expression in transgenic corn plants by cloning it in the appropriate corn gene expression vector.

EXAMPLE 7

USE OF THE ARABIDOPSIS THALIANA DELTA-15 DESATURASE GENOMIC CLONES AS A RESTRICTION FRAGMENT LENGTH POLYMORPHISM (RFLP) MARKERS TO MAP THE DELTA-15 DESATURASE LOCI IN ARABIDOPSIS

DNA flanking the T-DNA insertion site in mutant line 3707 was used to map the genetic locus encoding the delta-15 desaturase of *Arabidopsis thaliana* seeds. An approximately 12 kB genomic DNA fragment containing the *Arabidopsis* delta-15 desaturase coding sequence was removed from the lambda-4211 clone by digestion with restriction endonuclease Xho I, separated from the Lambda arms by agarose gel electrophoresis, and purified using standard procedures. The isolated DNA was labeled with ^{32}P using a random priming kit from Pharmacia under conditions recommended by the manufacturer. The radioactive DNA was used to probe a Southern blot containing genomic DNA from *Arabidopsis thaliana* (ecotype Wassileskija and marker line W100 ecotype Landesberg background) digested with one of several restriction endonucleases. Following hybridization and washes under standard conditions (Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press), autoradiograms were obtained. Different patterns of hybridization (polymorphisms) were identified in digests using restriction endonucleases Bgl II, Cla I, Hind III, Nsi I, and Xba I. The same radiolabeled DNA fragment was used to map the polymorphism essentially as described by

Helentjaris et al., (Theor. Appl. Genet. (1986) 72:761-769). The radiolabeled DNA fragment was applied as described above to Southern blots of Xba I digested genomic DNA isolated from 117 recombinant inbred progeny (derived from single-seed descent lines to the F_6 generation) resulting from a cross between Arabidopsis thaliana marker line W100 and ecotype Wassileskija (Burr et al., Genetics (1988) 118:519-526). The bands on the autoradiograms were interpreted as resulting from inheritance of either paternal (ecotype Wassileskija) or maternal (marker line W100) DNA or both (a heterozygote). The resulting segregation data were subjected to genetic analysis using the computer program Mapmaker (Lander et al., Genomics (1987) 1:174-181). In conjunction with previously obtained segregation data for 63 anonymous RFLP markers and 9 morphological markers in Arabidopsis thaliana (Chang et al., Proc. Natl. Acad. Sci. USA (1988) 85:6856-6860; Nam et al., Plant Cell (1989) 1:699-705), a single genetic locus was positioned corresponding to the genomic DNA containing the delta-15 desaturase coding sequence. The location of the delta-15 desaturase gene was thus determined to be on chromosome 2 between the lambda AT283 and cosmid c6842 RFLP markers, near the py and erecta morphological markers.

The cDNA in plasmid pCM2 was also shown to hybridize polymorphically to genomic DNA from Arabidopsis thaliana (ecotype Wassileskija and marker line W100 ecotype Landesberg background) digested with Eco RI. It was used as a RFLP marker to map the genetic locus for the gene encoding this fatty acid desaturase in Arabidopsis as described above. A single genetic locus was positioned corresponding to this desaturase cDNA. Its location was thus determined to be on chromosome 3 between the lambda AT228 and cosmid c3838

RFLP markers, "north" of the glabrous locus (Chang et al., Proc. Natl. Acad. Sci. USA (1988) 85:6856-6860; Nam et al., Plant Cell (1989) 1:699-705).

EXAMPLE 8

USE OF SOYBEAN SEED MICROSOMAL DELTA-15 GLYCEROLIPID DESATURASE cDNA SEQUENCE IN PLASMID AS A RESTRICTION FRAGMENT LENGTH POLYMORPHISM (RFLP) MARKER

A 600 bp fragment of the cDNA insert from plasmid pXF1, which contains about 300 bp of the coding sequence and 300 bp of the 3' untranslated sequence, was excised by digestion with restriction enzyme Eco RI in standard conditions as described in Sambrook et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press), purified by agarose gel electrophoresis and labeled with ^{32}P using a Random Priming Kit from Bethesda Research Laboratories under conditions recommended by the manufacturer. The resulting radioactive probe was used to probe a Southern blot (Sambrook et al., Molecular Cloning, A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press) containing genomic DNA from soybean [Glycine max (cultivar Bonus) and Glycine soja (PI81762)], digested with one of several restriction enzymes. After hybridization and washes under standard conditions (Sambrook et al. Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press), autoradiograms were obtained and different patterns of hybridization (polymorphisms) were identified in digests performed with restriction enzymes Bam HI, Eco RV and Eco RI. The same probe was then used to map the polymorphic pXF1 locus on the soybean genome, essentially as described by Helentjaris et al. (Theor. Appl. Genet. (1986) 72:761-769). Plasmid pXF1/600 bp probe was applied, as described above, to Southern blots of EcoRI, PstI, EcoRV, BamHI, or Hin DIII digested

genomic DNAs isolated from 68 F2 progeny plants resulting from a *G. max* Bonus x *G. soja* PI81762 cross. The bands on the autoradiograms were interpreted as resulting from the inheritance of either paternal (Bonus) or maternal (PI81762) pattern, or both (a heterozygote). The resulting data were subjected to genetic analysis using the computer program Mapmaker (Lander et al., Genomics (1987) 1:174-181). In conjunction with previously obtained data for 436 anonymous RFLP markers in soybean (Tingey et al., J. Cell. Biochem., Supplement 14E (1990) p. 291, abstract R153], Applicants were able to position a single genetic locus corresponding to the pXF1/600 bp probe on the soybean genetic map. This confirms that the gene for microsomal delta-15 desaturase is located on chromosome 19 in the soybean genome. This information will be useful in soybean breeding targeted towards developing lines with altered polyunsaturate levels.

EXAMPLE 9

OVEREXPRESSION OF MICROSOMAL DELTA-15 FATTY ACID DESATURASE IN PLANTS

Detailed procedures for DNA manipulation, such as use of restriction endonucleases and other DNA modifying enzymes, agarose gel electrophoresis, isolation of DNA from agarose gels, transformation of *E. coli* cells with plasmid DNA, and isolation and sequencing of plasmid DNA are described in Sambrook et al. (1989) Molecular cloning, A Laboratory Manual, 2nd ed. Cold Spring Harbor Laboratory Press and Ausubel et al. (1989) Current Protocols in Molecular Biology John Wiley & Sons. All restriction enzymes and modifying enzymes were obtained from Bethesda Research Laboratory, unless otherwise noted.

To test the biological effect of overexpression of the microsomal delta-15 desaturase SEQ ID NO:1, i.e., the cDNA encoding *Arabidopsis thaliana* microsomal delta-15 desaturase, was placed in the sense orientation behind either the CaMV 35S promotor, to provide constituitive expression, or behind the promotor for the gene encoding soybean a' subunit of the β-conglycinin (7S) seed storage protein, to provide embryo-specific expression. To create the chimeric gene constructs, specific expression cassettes were made to facilitate easy manipulation of the desired clones. The chimeric genes were then transformed into plant cells by *Agrobacterium tumefaciens*'s binary Ti plasmid vector system [Hoekema et al,. (1983) Nature 303:179-180; Bevan (1984) Nucl. Acids Res. 12:8711-8720].

Overexpression of Arabidopsis Delta-15 Fatty Acid Desaturase in Transgenic Carrot Hairy Roots

To confirm the identity of SEQ ID NO:1 (Arabidopsis microsomal delta-15 fatty acid desaturase) and to test the biological effect of its overexpression in a heterologous plant species, the constitutive chimeric gene 35S:SEQ ID NO:1 was introduced into carrot tissue by Agrobacterium. The cassette for constitutive gene expression in plasmid, pAW28, originated from pK35K which, in turn, is derived from pKNK. Plasmid pKNK is a pBR322-based vector containing a chimeric gene for plant kanamycin resistance: nopaline synthase (NOS) promoter/neomycin phosphotransferase (NPT) II coding region/3' NOS chimeric gene. Plasmid pKNK has been deposited on 7 January 1987 with the American Type Culture Collection of Rockville,Maryland, USA under the provisions of the Budapest Treaty and bears the deposit accession number 67284. A map of this plasmid is shown in Lin, et al., Plant Physiol. (1987) 84:856-861. The NOS promoter region is a 296 bp Sau 3A-Pst I fragment

corresponding to nucleotides -263 to +33, with respect to th transcription start sit , of the NOS gene described by Depicker et al. (1982) J. Appl. Genet. 1:561-574. The Pst I site at the 3' end was created at the translation initiation codon of the NOS gene. The NptII coding region is a 998 bp Hind III-Bam HI fragment obtained from transposon Tn5 (Beck et al., Gene (1982) 19:327-336) by the creation of Hind III and Bam HI sites at nucleotides 1540 and 2518, respectively. The 3' NOS is a 702 bp Bam HI-Cla I fragment from nucleotides 848 to 1550 of the 3' end of the NOS gene (Depicker et al., J. Appl. Genet. (1982) 1:561-574) including its' polyadenylation region. pKNK was converted to pK35K by replacing its Eco RI-Hind III fragment containing the NOS promoter with a Eco RI-Hind III fragment containing the CaMV 35S promoter. The Eco RI-Hind III 35S promoter fragment is the same as that contained in pUC35K that has been deposited on 7 January 1987 with the American Type Culture Collection under the provisions of the Budapest Treaty and bears the deposit accession number 67285. The 35S promoter fragment was prepared as follows, and as described in Odell et al., Nature (1985) 313:810-813, except that the 3' end of the fragment includes CaMV sequences to +21 with respect to the transcription start site. A 1.15 KB Bgl II segment of the CaMV genome containing the region between -941 and +208 relative to the 35S transcription start site was cloned in the Bam HI site of the plasmid pUC13. This plasmid was linearized at the Sal I site in the polylinker located 3' to the CaMV fragment and the 3' end of the fragment was shortened by digestion with nuclease Bal31. Following the addition of Hind III linkers, the plasmid DNA was recircularized. From nucleotide sequence analysis of the isolated clones, a 3' deletion fragment was selected with the Hind III

linker positioned at +21. The 35S promoter fragment was isolated as an Eco RI-Hind III fragment, the Eco RI site coming from the polylinker of pUC13.

The NPTII coding region in plasmid pK35K was removed from plasmid pK35K by digestion with Hind III and Bam HI restriction enzymes. Following digestion, the ends of the DNA molecules were filled-in using Klenow enzyme. Not I linkers (New England Biolabs) were then ligated on the ends and the plasmid was recircularized to yield plasmid pK35Nt. A 1.7 kB fragment containing the 35S promotor region - Not I site - 3' untranslated region from nopaline synthase was liberated from pK35Nt using restriction endonucleases Eco RI and Cla I. Following restriction digestion the ends of the DNA molecules were filled-in using Klenow enzyme after which Xho I linkers (New England Biolabs) were added. The 1.7 kB fragment, now containing Xho I sites at either end, was gel isolated and cloned into the plasmid vector pURA3 (Clonetech) at its unique Xho I site. The vector pURA3 was choosen due to the absence of a Not I restriction site, the presence of a single Xho I restriction site and because the relatively large size of the vector (pURA3) would make the isolation of the gene expression cassettes relatively easy from the final construct.

The 1.4 kB Not I fragment in plasmid pCF3 containing Arabidopsis microsomal delta-15 desaturase (SEQ ID NO:1) was isolated and ligated to pAW28 (the constituitive expression cassette) previously linearized with Not I restriction enzyme and treated with calf intestinal alkaline phosphatase (Boehringer Mannheim) to result in plasmids pAW29 and pAW30 that had SEQ ID NO:1 cloned in a sense orientation and antisense orientation, respectively, with respect to the promoter. The orientation of the cDNA relative to the promotors was

established by digestion with appropriate restriction endonucleases or by sequencing across the promotor-cDNA junctions.

The chimeric genes 35S promotor/sense SEQ ID NO:1/3'NOS and 35S promotor/antisense SEQ ID NO:1/3'NOS were isolated as a 3 kB Xho I fragment from plasmids pAW29 and pAW30, respectively, and cloned into the binary vector pZS194b at its unique Sal I site to result in plasmids pAW31 and pAW32, respectively. The orientation of the plant selectable marker gene in pAW31 and pAW32 is the same as that of the 35S promoter as acertained by digestion with appropriate restriction endonucleases. Binary vector pZS194b contains the pBR322 origin of replication, the replication and stability regions of the _Pseudomonas aeruginosa_ plasmid pVS1 [Itoh, et al., (1984) Plasmid 11:206-220] required for replication and maintenance of the plasmid in _Agrobacterium_, the bacterial NPT II gene (kanamycin resistance) from Tn5 [Berg et al., (1975) Proc. Nat'l. Acad. Sci. U.S.A. 72:3628-3632] as a selectable marker for transformed bacteria, left and right borders of the T-DNA of the Ti plasmid [Bevan et al., (1984) Nucl. Acids Res. 12:8711-8720], and, between the left and right T-DNA borders are the chimeric NOS:NPT II gene for plant kanamycin resistance, described above, as a selectable marker for transformed plant cells and the E. coli lacZ a-complementing segment [Vieria and Messing (1982) Gene 19:259-267] with unique restriction endonuclease sites for Kpn I and Sal I.

The binary vectors pAW31 and pAW32 were transformed by the freeze/thaw method [Holsters et al. (1978) Mol. Gen. Genet. 163:181-187] into _Agrobacterium tumefaciens_ strain R1000, carrying the Ri plasmid pRiA4b from _Agrobacterium rhizogenes_ [Moore et al., (1979) Plasmid

2:617-626] to result in transformants R1000/pAW31 and R1000/pAW32, respectively.

Carrot (Daucus carota L.) cells were transformed by co-cultivation of carrot root disks with strain R1000, R1000/pAW31, or R1000/pAW32 by the method of Petit et al., (1986) Mol. Gen. Genet. 202:388-393]. To prepare explants for inoculation, carrots purchased from the local supermarket were first scrubbed gently with water and dish detergent, then rinsed thoroughly with tap and distilled water. They were surface sterilized in a stirred solution of 50% Clorox and distilled water for 30 min and rinsed thoroughly with sterile distilled water. The carrots were peeled using an autoclaved vegetable peeler and then sliced with a scalpel blade into disks of approximately 5-10 mm thickness. The disks were placed in petri dishes, onto a medium consisting of distilled deionized water solidified with 0.7% agar, in an inverted orientation so that the cut surface nearest to the root apex of the carrot was exposed for inoculation.

Cultures of Agrobacterium strains R1000, R1000/pAW31, and R1000/pAW32 were initiated from freshly grown plates in LB broth plus the appropriate antibiotic selective agents (50 mg/L chloramphenicol for the R1000 or 50 mg/L each of chloramphenicol and kanamycin for R1000/pAW31 and R1000/pAW32) and grown at 28°C to an optical density of around 1.0 at 600 nm. Bacterial cells were pelleted by centrifugation, rinsed and resuspended in LB broth without antibiotics. Freshly cut carrot disks were inoculated by applying 100 µL of the bacterial suspension to the cut surface of each disk. As a control, some disks were inoculated with sterile LB broth only, to indicate the extent of root formation in the absence of Agrobacterium.

Inoculated root disks were incubated at 25°C in the dark in petri dishes sealed with Parafilm. After two weeks of co-cultivation of carrot disks with Agrobacterium, the carrot disks were transferred to fresh agar-solidified water medium containing 500 mg/L carbenicillin for the counterselection of Agrobacterium. At this time, hairy root formation was noted on some root disks. Transfer of the explants to fresh counterselection medium was done at four weeks. Excision of individual roots from the explants was begun at six weeks. Ten days later, additional roots were taken from the explants as needed.

Approximately 5-10 mm long hairy roots were excised and individually subcultured on MS minimal organics medium with 30 g/L sucrose (Gibco, Grand Island, N. Y., Cat. No. 510-1118EA) and 500 mg/L carbenicillin. Approximately equal numbers of roots were subcultured in liquid medium and in a medium solidified with 0.6% agarose. Cultures on solid medium were grown in 60 x 100 mm petri dishes, liquid cultures were in 6-well culture dishes. When excising roots, an effort was made to select single roots from distinct callus-like outgrowths on the wounded surface. These sites of excision were marked on the lid of the petri dish to minimize repeat sampling of tissue originating from the same transformation event.

Two to three weeks after excision from the explants, individual hairy root cultures that were not visibly contaminated with Agrobacterium were transferred to fresh MS medium supplemented with 500 mg/L carbenicillin. The root mass of each culture was cut into segments including one or more branch roots, and these segments were transferred as a group to a plate or well of fresh medium. Approximately 20 mg fresh weight of tissue of root cultures which grew to adequate size

within the next two to three weeks were sampled for fatty acid composition by gas chromatography of the fatty acyl methyl esters essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H_2SO_4 in methanol was used as the methylation reagent and samples were heated for 1.5 h at 80°C to effect the methanolysis of the seed triglycerides. The results are shown in Table 6. A second sample of tissue consisting of an actively growing root tip of approximately 1 cm was excised and placed on MS medium supplemented with 500 mg/L carbenicillin and 25-50 mg/L kanamycin to test for kanamycin resistance select for hairy roots co-transformed with the binary vector [Simpson et al. (1986) Plant Mol. Biol. 6:403-415].

The ability of R1000 transformed "hairy" roots to grow in the absence of exogenous phytohormones can be attributed to the Ri plasmid, pRiA4b. When R1000/pAW31 or R1000/pAW32 strains are used to transform, only a fraction (about half) of the "hairy" roots will also be

transformed with the experimental binary vector, pAW31 or pAW32. Thus, as expected, not all hairy roots resulting from transformation with R1000/pAW31 show the high 18:3 phenotype. The absense of any significant fatty acid phenotype in "hairy roots" transformed with R1000/pAW31 is expected, since carrot and Arabidopsis delta-15 desaturase sequences are not expected to be sufficiently related. These results show that overexpression of Arabidopsis microsomal delta-15 desaturase can result in over 10-fold increase in 18:3 at the expense of 18:2 in heterologous plant tissue.

Overexpression of Arabidopsis Delta-15 Fatty Acid Desaturase in Seeds and Complementation of the Mutation in Delta-15 Desaturation in Mutant 3707

To complement the delta-15 desaturation mutation in the T-DNA mutant 3707 and to test the biological effect of overexpression of SEQ ID NO:1 (Arabidopsis microsomal delta-15 fatty acid desaturase) in seed, the embryo-specific promoter:SEQ ID NO:1 chimeric gene was transformed into the mutant plant. This embryo-specific expression cassette in pAW42 was produced, in part, using a modified version of vector pCW109. Vector pCW109 itself was made by inserting into the Hind III site of the cloning vector pUC18 (Bethesda Research Laboratory) a 555 bp 5' non-coding region (containing the promoter region) of the β-conclycinin gene followed by the multiple cloning sequence containing the restriction endonuclease sites for Nco I, Sma I, Kpn I and Xba I, then 1174 bp of the common bean phaseolin 3' untranslated region into the Hind III site [Slightom et al., Proc. Nat'l Acad. Sci. U.S.A. (1983) 80:1897-1901]. The β-conclycinin promoter region used is an allele of the published β-conglycinin gene (Doyle et al., J. Biol. Chem. (1986) 261:9228-9238) due to differences at 27

nucl otide positions. Further sequence description may be found in Slightom (W091/13993).

The modifications to vector pCW109 were as follows: The potential translation start site was destroyed by digestion with Nco I and Xba I restriction enzymes followed by treatment with mung bean nuclease (New England Biolabs) to create linear, blunt ended DNA molecules. After ligation of Not I linkers (New England Biolabs) and digestion with Not I restriction enzyme (New England Biolabs) the plasmid was recircularized. Confirmation of the desired change was obtained by dideoxy sequencing. The resulting plasmid was designated pAW35. The 1.8 kB Hind III fragment from pAW35 containing the modified β-conclycinin promotor/3' phaseolin region was subcloned into the Hind III site in plasmid vector pBluescript SK$^+$ (Stratagene) creating plasmid pAW36. Plasmid pAW36 was linerized at its unique Eco RI site and ligated to Eco RI/Xho I adaptors (Stratagene). Following digestion with Xho I, the 1.7 kB Xho I fragment containing the β-conclycinin promotor/Not I site/3'-phaseolin untranslated region was cloned into the Xho I site in pURA3 vector (Clonetech). The resultant plasmid, pAW42, contains the seed specific expression cassette bordered by Xho I sites to facilitate cloning into modified T-DNA binary vectors and a unique Not I site to facilitate cloning of target cDNA sequences. Vector pURA3 was choosen due to the absence of a Not I restriction site, the presence of a single Xho I restriction site, and the relatively large size of the vector (pURA3) would make the isolation of the gene expression cassettes relatively easy from the final construct.

The 1.4 kB Not I fragment in plasmid pCF3 containing Arabidopsis microsomal delta-15 desaturase (SEQ ID NO:1) was isolated and ligated to plasmid pAW42

(the seed-specific expression cassette) that had pr viously been linearized with Not I restriction enzyme and treated with calf intestinal alkaline phosphatase (Boehringer Mannheim) to result in plasmids pAW45 that had SEQ ID NO:1 cloned in a sense orientation with respect to the promoter. The orientation of the cDNA relative to the promotors was established by digestion with appropriate restriction endonucleases or by sequencing across the promotor-cDNA junctions.

The chimeric β-conclycinin promotor/sense SEQ ID NO:1/phaseolin 3' was isolated as a 3.2 kB Xho I fragment from plasmid pAW45 and subcloned into the binary vector pAW25 at its unique Sal I site. In the resulting vector, pAW50, the orientation of the plant selectable marker is the same as that of the β-conclycinin promoter as acertained by digestion with appropriate restriction endonucleases. Plasmid pAW25, is derived from plasmids pZS94K and pML2. Plasmid pZS94K contains the pBR322 origin of replication, the replication and stability regions of the Pseudomonas aeruginosa plasmid pVS1 [Itoh, et al., (1984) Plasmid 11:206-220] required for replication and maintenance of the plasmid in Agrobacterium, the bacterial NPT II gene (kanamycin resistance) from Tn5 [Berg et al., (1975) Proc. Nat'l. Acad. Sci. U.S.A. 72:3628-3632] as a selectable marker for transformed bacteria, a T-DNA left border fragment of the octopine Ti plasmid pTiA6 and right border fragment derived from TiAch5 describe by van den Elzen et al. (Plant Mol. Biol. (1985) 5:149-154). Between these borders are the E. coli lacZ a-complementing segment [Vieria and Messing (1982) Gene 19:259-267] with restriction endonuclease sites Sal I and Asp 718 derived from pUC18. A 4.5 kB Asp 718-Sal I DNA fragment containing the chimeric herbicide sulfonylurea (SU)-resistant acetolactate (ALS) gene was

obtained from plasmid pML2 and cloned into the Asp 718-Sal I sites of plasmid pZS94K. This chimeric ALS gene contained the CaMV 35S promoter/Cab22L Bgl II-Nco I fragment that is described by Harpster et al., [Mol. Gen. Genet. (1988) 212:182-190] and the Arabidopsis ALS coding and 3' non-coding sequences [Mazur et al., (1987) Plant Physiol. 85:1110-1117] that was mutated so that it encodes a SU-resistant form of ALS. The mutation, introduced by site-directed mutagenesis, are those present in the tobacco SU-resistant Hra gene described by Lee et al., (1988) EMBO J. 5:1241-1248. The resulting plasmid was designated pAW25.

The binary vector pAW25 containing the chimeric embryo-specific β-conglycinin promotor:sense SEQ ID NO:1 gene was transformed by the freeze/thaw method [Holsters et al., (1978) Mol. Gen. Genet. 163:181-187] into the avirulent Agrobacterium strain LBA4404/pAL4404 [Hoekema et al., (1983) Nature 303:179-180].

Arabidopsis root cultures were transformed by co-cultivation with Agrobacterium using standard aseptic techniques for the manipulation of sterile media and axenic plant/bacterial cultures were followed, including the use of a laminar flow hood for all transfers. Compositions of the culture media are listed in Table 8. Unless otherwise indicated, 25x100 mm petri plates were used for plant tissue cultures. Incubation of plant tissue cultures was at 23°C under constant illumination with mixed fluorescent and "Gro and Sho" plant lights (General Electric) unless otherwise noted. To initiate *in vitro* root cultures of the T-DNA homogyzous mutant line 3707 (*Arabidopsis thaliana* (L.) Heynh, geographic race Wassilewshija) seeds of the mutant line were sterilized for 10 min in a solution of 50% Chlorox with 0.1% SDS, rinsed 3 to 5 times with sterile dH_2O, dried thoroughly on sterile filter paper, and then 2-3 seeds

were sown in liquid B5 medium in 250 mL Belco flasks. The flasks were capped, placed on a rotary shaker at 70-80 rpm, and incubated for 3-4 weeks. Prior to inoculation with Agrobacterium, root tissues were cultured on callus induction medium (MSKig). Roots were harvested by removing the root mass from the Belco flask, placing it in a petri dish, and, using forceps, pulling small bundles of roots from the root mass and placing them on MSKig medium. Petri dishes were sealed with filter tape and incubated for four days.

Agrobacterium strain LBA4404 carrying the plasmids pAL4404 and pAW50 were grown in 5 mL of YEB broth containing 25 mg/L kanamycin and 100 mg/L rifampicin. The culture was grown for approximately 17-20 h in glass culture tubes in a New Brunswick platform shaker (225 rpm) maintained at 28°C. Pre-cultured roots were cut into 0.5 cm segments and placed in a 100 µm filter, made from a Tri-Pour beaker (VWR Scientific, San Francisco, CA USA) and wire mesh, which is set in a petri dish. Root segments were inoculated for several min in 30-50 mL of a 1:20 dilution of the overnight Agrobacterium culture with periodic gentle mixing. Inoculated roots were transferred to sterile filter paper to draw off most of the liquid. Small bundles of roots, consisting of several root segments, were placed on MSKig medium containing 100 µM acetosyringone (3',5'-Dimethoxy-4'-hydroxyaceto-phenone, Aldrich Chemical Co., Milwaukee, WI, USA). Petri plates were sealed with parafilm or filter tape and incubated for 2 to 3 days.

After infection, root segments were rinsed and transferred to shoot induction medium with antibiotics. Root bundles were placed in a 100 µm filter unit (described above) and rinsed with 30-50 mL liquid MSKig medium. The filter was vigorously shaken in the solution to help remove the Agrobacterium, transferred

to a clean petri dish, and rinsed again. Roots were blotted on sterile filter paper and bundles of roots were placed on MSg medium containing 500 mg/l vancomycin and either 10 or 20 ppb chlorsulfuron. Plates were sealed with filter tape and incubated for 12 to 14 days.

Green nodules and small shoot primordia were visible at about 2-3 weeks. The explants were either left intact or were broken into numerous pieces and placed on GM medium containing 200-300 mg/L vancomycin and either 10 or 20 ppb chlorsulfuron for further shoot development. Plates were either sealed with two pieces of tape or with filter tape. As they developed, individual shoots were isolated from the callus and were placed on MSRg medium containing 100 mg/L vancomycin and either 10 or 20 ppb chlorsulfuron. Dishes were sealed as described above and incubated for seven to 10 days. Shoots were then transferred to GM medium containing 100-200 mg/L vancomycin in 25x100 petri dishes or Magenta G7 vessels. Many primary transformants (T1) which were transferred to individual containers set seed (T2).

T2 seed was harvested from selected putative transformants and sown on GM medium containing 10ppb chlorsulfuron. Plates were sealed with filter tape, cold treated for 2 or more days at 4°C, and then incubated for 10 to 20 days at 23°C under constant illumination as described above. Seedlings were scored as resistant (green, true leaves develop) and sensitive (no true leaves develop).

Selected chlorsulfuron resistant T2 seedlings were transplanted to soil and were grown to maturity at 23°C daytime (16 h) 18°C nighttime (8 h) at 65-80% relative humidity.

T2 seeds from two plants were harvested at maturity and analysed individually for fatty acid composition by

gas chromatography of the fatty acyl methyl esters essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H_2SO_4 in methanol was used as the methylation reagent and samples were heated for 1.5 h at 80°C to effect the methanolysis of the seed triglycerides. The results are shown in Table 7.

TABLE 7

Percent Fatty Acid in Seeds of Transgenic Mutant 3707

Seed Sample	16:0	18:0	18:1	18:2	18:3
wildtype (6)	6	4	14	30	19
mutant 3707 (6)	6	4	14	44	3
1-1	10	4	22	9	55
1-2	11	6	22	14	48
1-3	12	7	16	6	57
1-4	10	4	30	52	4
1-5	10	4	18	17	48
1-6	10	5	15	15	53
2-1	11	5	19	60	4
2-2	10	5	19	9	56
2-3	9	4	27	8	52
2-4	10	5	17	10	56
2-5	10	5	19	9	56
2-6	10	5	17	17	48

The fatty acid composition of the wild-type and mutant line 3707 represents the average of 6 single seeds each. Seeds from plant 1 are designated 1-1 to 1-6 and those from plant 2 are designated 2-1 to 2-6. The 20:1 and 20:2 amounts are not shown. The data shows that the one out of six seeds in each plant show the mutant fatty acid phenotype, while the remaining seeds show more than 10-fold increase in 18:3 to ca.55%. While most of the increase occurs at the expense of 18:2, some of it also occurs at the expense of 18:1.

Such high levels are of linolenic acid in vegetable oils are observed in specialty oil crops, such as linseed. Thus, overexpression of this gene in other oilscrops, especially canola, which is a close relative of Arabidopsis, is also expected to result in such high levels of 18:3.

EXAMPLE 10

Construction of Vectors for Transformation of *Brassica napus* for Reduced Expression of Delta-15 Desaturases in Developing Seeds

Detailed procedures for manipulation of DNA fragments by restriction endonuclease digestion, size separation by agarose gel electrophoresis, isolation of DNA fragments from agarose gels, ligation of DNA fragments, modification of cut ends of DNA fragments and transformation of *E. coli* cells with circular DNA plasmids are all described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed (1989) Cold Spring Harbor Laboratory Press) and Ausubel et al., Current Protocols in Molecular Biology (1989) John Wiley & Sons).

Sequences of the cDNA's encoding the *B. napus* cytoplasmic delta-15 desaturase and the *Brassica napus* plastid delta-15 desaturase were placed in the antisense orientation behind the promoter region from the a' subunit of the soybean storage protein β-conglycinin to provide embryo specific expression and high expression levels.

An embryo-specific expression cassette was constructed to serve as the basis for chimeric gene constructs for anti-sense expression of the nucleotide sequences of delta-15 desaturase cDNAs. The vector pCW109 was produced by the insertion of 555 base pairs of the β-conglycinin (a' subunit of the 7s seed storage protein) promoter from soybean (*Glycine max*), the β-conglycinin 5' untranslated region followed by a multiple cloning sequence containing the restriction endonuclease sites for Nco I, Sma I, Kpn I and Xba I, then 1174 base pairs of the common bean phaseolin 3' untranslated region into the Hind III site in the cloning vector pUC18 (BRL). The β-conglycinin promoter

sequence represents an allele of the published β-conglycinin gene (Doyle et al., (1986) J. Biol. Chem. 261:9228-9238) due to differences at 27 nucleotide positions. Further sequence description may be found in Slightom (WO91/13993). The sequence of the 3' untranslated region of phaseolin is described in (Slightom et al.,(1983) Proc. Natl. Acad. Sci. USA, 80:1897-1901).

To facilitate use in antisense constructions, the Nco I site and potential translation start site in the plasmid pCW109 was destroyed by digestion with Nco I, mung bean exonuclease digestion and re-ligation of the blunt site to give the modified plasmid pCW109A. pCW109A was opened between the β-conglycinin promoter sequence and the phaseolin 3' sequence by digestion with Sma I to allow insertion of blunt ended cDNA fragments encoding the delta-15 desaturase sequences by ligation. The blunt ended fragment of the cytoplasmic delta-15 desaturase was obtained from plasmid pBNSF3, which contains the nucleotides 208 to 1336 of the cDNA insert described in SEQ ID NO:6. pBNSF3 was modified to remove the Hind III site at bases 682 to 687 of SEQ ID 6 by digesting with Hind III, blunting with Klenow and re-ligating. The resulting plasmid [pBNSF3(-H)], was digested with Eco RI and Xho I to release the delta-15 cDNA fragment, all ends were Klenow blunted and the 1.2 kB coding region was purified by gel isolation. The 1.2 kB fragment was ligated into the Sma I cut pCW109A described above. The antisense orientation of the inserted cDNA relative to the β-conglycinin promoter was established by digestion with Aat I which cuts in the delta-15 desaturase coding region and in the vector 5' to the β-conglycinin promoter to release a 1.4 Kb fragment when the coding region is in the antisense

orientation. The antisense construction was given the name pCCFdR1.

The transcription unit [β-conglycinin promoter:antisense delta-15 desaturase:phaseolin 3'end] was released from pCCFdR1 by Hind III digestion, isolated,and ligated into pBluescript which had also been Hind III digested to give plasmid pCCFdR2. This construct has unique BamH I and Sal I sites which were digested. The 3 kB transcriptional unit was isolated and cloned into the Bam HI and Sal I sites in pZ199 described below to give the binary vector pZCC3FdR. The orientation given by this directional cloning is with transcription of both the selectable marker gene and the delta-15 antisense gene in the same direction and toward the right border tDNA sequence.

An antisense construction based on the plastid delta-15 desaturase was made with the 425 most 3' bases of SEQ ID NO:8 which is contained in the plasmid pBNSFD-8. pBNSFD-8 represents a cDNA of the plastid delta-15 desaturase in pBluescript. The cDNA insert was removed from pBNSFD-8 by digestion with Xho I and Sma I, the fragments were blunted, and the 425 base insert isolated by gel purification. The isolated fragment was cloned into the Sma I site of pCW109A and the antisense orientation of the chosen clone confirmed by digestion of the plasmid with Pst I. Pst I cuts in the plastid delta-15 sequence and in the pCW109A vector 5' to the β-conglycinin promoter to release a 1.2 kB fragment indicative of the antisense orientation. The plasmid containing this construction was called pCCdFdR1.

Digestion of pCCdFdR1 with Hind III removes a 2.3 kB fragment containing the transcriptional unit [β-conglycinin promter:plastid delta-15 antisense:3'-phaseolin sequence]. The fragment was gel isolated and cloned into Hind III digested pBluescript. The

orientation of the fragment was relative to the Bam HI site in the cloning region of pBluescript was determined by digestion with Pst I as described above. A clone oriented with the promoter toward the Sal I containing end was chosen and given the name pCCdFdR2.

pCCdFdR2 was digested with Bam HI and Sal I, the released fragment was gel isolated and ligated into pZ199 which had been digested with Bam HI and Sal I to give the binary vector pZCCdFdR.

Vectors for transformation of the antisense delta-15 desaturase constructions under control of the β-conglycinin promoter into plants using Agrobacterium tumefaciens were produced by constructing a binary Ti plasmid vector system (Bevan, (1984) Nucl. Acids Res. 12:8711-8720). The starting vector used for these systems (pZS199) is based on a vector which contains: (1) the chimeric gene nopaline synthase/neomycin phosphotransferase as a selectable marker for transformed plant cells (Bevan et al., (1984) Nature 304:184-186), (2) the left and right borders of the T-DNA of the Ti plasmid (Bevan et al., (1984) Nucl. Acids Res. 12:8711-8720), (3) the E. coli lacZ a-complementing segment (Vieria and Messing (1982) Gene 19:259-267) with unique restriction endonuclease sites for Eco RI, Kpn I, Bam HI, Hin DIII, and Sal I, (4) the bacterial replication origin from the Pseudomonas plasmid pVS1 (Itoh et al., (1984) Plasmid 11:206-220), and (5) the bacterial neomycin phosphotransferase gene from Tn5 (Berg et al., (1975) Proc. Natnl. Acad. Sci. U.S.A. 72:3628-3632) as a selectable marker for transformed A. tumefaciens. The nopaline synthase promoter in the plant selectable marker was replaced by the 35S promoter (Odell et al. (1985) Nature, 313:810-813) by a standard restriction endonuclease digestion and ligation strategy. The 35S promoter is

required for efficient *Brassica napus* transformation as described below.

EXAMPLE 11

AGROBACTERIUM MEDIATED TRANSFORMATION OF *BRASSICA NAPUS*

The binary vectors pZCC3FdR abd pZCCdFdR were transferred by a freeze/thaw method (Holsters et al., (1978) Mol Gen Genet 163:181-187) to the *Agrobacterium* strain LBA4404/pAL4404 (Hoekema et al., (1983), Nature 303:179-180).

Brassica napus cultivar "Westar" was transformed by co-cultivation of seedling pieces with disarmed *Agrobacterium tumefaciens* strain LBA4404 carrying the the appropriate binary vector.

B. napus seeds were sterilized by stirring in 10% Chlorox, 0.1% SDS for thirty min, and then rinsed thoroughly with sterile distilled water. The seeds were germinated on sterile medium containing 30 mM $CaCl_2$ and 1.5% agar, and grown for six days in the dark at 24°C.

Liquid cultures of *Agrobacterium* for plant transformation were grown overnight at 28°C in Minimal A medium containing 100 mg/L kanamycin. The bacterial cells are pelleted by centrifugation and resuspended at a concentration of 10^8 cells/mL in liquid Murashige and Skoog Minimal Organic medium containing 100 µM acetosyringone.

B. napus seedling hypocotyls were cut into 5 mm segments which were immediately placed into the bacterial suspension. After 30 min, the hypocotyl pieces were removed from the bacterial suspension and placed onto BC-12 callus medium containing 100 µM acetosyringone. The plant tissue and *Agrobacteria* were co-cultivated for three days at 24°C in dim light.

The co-cultivation was terminated by transferring the hypocotyl pieces to BC-12 callus medium containing

200 mg/L carbenicillin to kill the *Agrobacteria*, and 25 mg/L kanamycin to select for transformed plant cell growth. The seedling pieces were incubated on this medium for three weeks at 24°C under continuous light.

After three weeks, the segments wre transferred to BS-48 regeneration medium containing 200 mg/L carbenicillin and 25 mg/L kanamycin. Plant tissue was subcultured every two weeks onto fresh selective regeneration medium, under the same culture conditions described for the callus medium. Putatively transformed calli grow rapidly on regeneration medium; as calli reached a diameter of about 2 mm, they were removed from the hypocotyl pieces and placed on the same medium lacking kanamycin.

Shoots began to appear within several weeks after transfer to BS-48 regeneration medium. As soon as the shoots formed discernable stems, they were excised from the calli, transferred to MSV-1A elongation medium, and moved to a 16:8 h day/night photoperiod at 24°C.

Once shoots had elongated several internodes, they were cut above the agar surface and the cut ends were dipped in Rootone. Treated shoots were planted directly into wet Metro-Mix 350 soiless potting medium. The pots were covered with plastic bags which were removed when the plants were clearly growing -- after about 10 days.

Plants were grown under a 16:8 h day/night photoperiod, with a daytime temperature of 23°C and a nighttime temperature of 17°C. When the primary flowering stem began to elongate, it was covered with a mesh pollen-containment bag to prevent outcrossing. Self-pollination was facilitated by shaking the plants several times each day. Seeds derived from self-pollinations were harvested about three months after planting.

TABLE 9

Minimal A Bacterial Gr wth Medium

Dissolve in distilled water:

10.5 g potassium phosphate, dibasic

4.5 g potassium phosphate, monobasic

1.0 g ammonium sulfate

0.5 g sodium citrate, dihydrate

Make up to 979 mLs with distilled water

Autoclave

Add 20 mLs filter-sterilized 10% sucrose

Add 1 mL filter-sterilized 1 M $MgSO_4$

Brassica Callus Medium BC-12

Per liter:

Murashige and Skoog Minimal Organic Medium (MS salts, 100 mg/L i-inositol, 0.4 mg/L thiamine; GIBCO #510-3118)

30 sucrose

18 g mannitol

1.0 mg/L 2,4-D

3.0 mg/L kinetin

0.6% agarose

pH 5.8

Brassica Regeneration Medium BS-48

Murashige and Skoog Minimal Organic Medium Gamborg B5 Vitamins (SIGMA #1019)

10 g glucose

250 mg xylose

600 mg MES

0.4% agarose

pH 5.7

Filter-sterilize and add after autoclaving:

2.0 mg/L zeatin

0.1 mg/L IAA

Brassica Shoot Elongation Medium MSV-1A

Murashige and Skoog Minimal Organic Medium Gamborg B5 Vitamins

10 g sucrose

0.6% agarose

pH 5.8

EXAMPLE 12

ANALYSIS OF TRANSGENIC BRASSICA NAPUS PLANTS

Insertion of the intact antisense transcriptional unit was verified by Southern analysis using transgenic plant leaf tissue as the source of DNA as described in Example 5. Ten micrograms of leaf DNA was digested to completion with a mixture of Bam HI and Sal I

restriction endonucleases and then separatd by agarose gel electrophoresis. The separated DNA was transferred to Hybond H^+ membrane and hybridized with radiolabeled insert from pBNSF3-2. An estimate of the number of copies of the inserted transgene was made by calibrating each Southern blot with standard amounts of pBNSF3-2 corresponding to 1 and 5 copies per genome and comparing intensities of the autoradiographic signal from the standards, the endogenous delta-15 desaturase signals and the inserted gene signal. To date, 38 independent transformants have been analyzed for presence of the gene and 36 were found to be positive.

The relative content of the 5 most abundant fatty acids in canola seeds was determined either by direct trans-esterification of individual seeds in 0.5 mL of methanolic H_2SO_4 (2.5%) or by hexane extraction of bulk seed samples followed by trans-esterification of an aliquot in 0.8 mL of 1% sodium methoxide in methanol. Fatty acid methyl esters were extracted from the methanolic solutions into hexane after the addition of an equal volume of water.

The relative content of 18:3 fatty acid varies significantly during seed development. To a lesser extent, the ratio of 18:3 to 18:2 varies also. Thus meaningful data can be obtained only from seeds after maturation and drydown. Additionally, the ratio of 18:3 to total fatty acid content and to 18:0 varies significantly due to environmental factors, primarily temperature. In this circumstance, the most appropriate controls are the transformed plants which by Southern analysis do not contain the antisense delta-15 transgene. Analysis from the first 5 transformants to reach dry seed are given in Table 10 below. Seeds were harvested using a hand thesher, bulked and a 1.5 g (about 300 seeds) sample was taken. Seed from each

transformant was crushed with a mortar and pestel, extracted 4 times with 8 mL hexane at about 50°C. The combined extracts were reduced in volume to 5 mL and two 50 microliter aliquots were taken for esterification as described above. Separation of the fatty acid methyl esters was done by gas-liquid chromatography using an Omegawax 320 column (Supelco Inc., 0.32 mm ID X 30M) run isothermally at 220° and cycled to 260° between each injection.

TABLE 10

Transformant No.	% 18:3	%18:3/18:2	Antisense delta-15 Copy No.
pZCC3FdR-91	6.2	0.39	0
pZCC3FdR-81	5.9	0.33	1
pZCC3FdR-15	6.0	0.38	2
pZCC3FdR-11	5.6	0.34	1
pZCC3FdR-148	8.2	0.40	2

The differences between the 4 transformed lines and line 92 are very small, however to test the significance of the difference in the 18:3/18:2 ratio between line 81 and 91, 25 individual seeds from each line were trans-esterified and their fatty acid composition determined. The average ratio for line 81 was 0.345 with a coefficient of variation of 11.6% while the average for line 91 was 0.375 with a coefficient of variation of 8.0%. The sample means are significantly different at the 0.01% level using Student's t test.

EXAMPLE 13

CONSTRUCTION OF VECTORS FOR TRANSFORMATION OF GLYCINE MAX FOR REDUCED EXPRESSION OF DELTA-15 DESATURASES IN DEVELOPING SEEDS

The antisense G. max plastid delta-15 desaturase cDNA sequence under control of the β-conglycinin promoter was constructed using the vector pCW109A described in Example 10 above. For use in the soybean

transformation system described below, the transcriptional unit was placed in a vector along with an appropriate selectable marker expression system. The starting vector was pML45, which consists of the non-tissue specific and constitutive promoter designated 508D and described in Hershey (WO 9011361) driving expression of the neomycin phosphotransferase gene described in (Beck et al. (1982) Gene 19:327-336) followed by the 3' end of the nopaline synthase gene including nucleotides 848 to 1550 described by (Depicker et al. (1982) J. Appl. Genet. 1:561-574). This transcriptional unit was inserted into the commercial cloning vector pGEM9Z (BRL) and is flanked at the 5' end of the 508D promoter by the restriction sites Sal I, Xba I, Bam HI and Sma I in that order. An additional Sal I site is present at the 3' end of the NOS 3' sequence and the Xba I, Bam HI and Sal I sites are unique.

Removal of the unit[β-conglycinin promter:cloning region:phaseolin 3' end] from pCW109A by digestion with Hind III, blunting the ends and isolating the 1.8 kB fragment afforded the expression cassette pCST by ligating the above isolated fragment into the Sma I site of pML45. A clone with the β-conglycinin promoter in the same orientation as the 508D promoter were chosen by digestion with Xba I. The correct orientation releases a 700 bp fragment. This vector cassette was called pCST.

The 2.2 kB insert encoding the soybean, plastid delta-15 desaturase was subcloned from the plasmid pXF1 by digestion with HinP I to remove about 1 kB of unrelated cDNA. HinP I cuts within the cDNA insert very near the 5' end of the cDNA for the delta-15 desaturase and about 300 bp from the 3' end of that cDNA. The Cla I compatable ends were cloned into Cla I digested pBluescript and a clone with the 5' end of the cDNA

toward the Eco RV site in the pBluescript cloning region was selected based on the relaese of a 900 bp fragment by digestion with Pst I. The subcloned plasmid was called pS3Fd1.

The delta-15 encoding sequence was removed from pS3Fd1 by digestion with HinC II and Eco RV, the 2.2 kB fragment was gel isolated and cloned into the opened Sma I site in pCST1. A clone with the delta-15 sequence in the antisense orientation to the β-conglycinin promoter was selected by digestion with Xba I. The antisense construct releases a 400 bp piece and that clone was designated pCS3FdST1R.

EXAMPLE 14

TRANSFORMATION OF SOMATIC SOYBEAN EMBRYO CULTURES

Soybean embryogenic suspension cultures are maintained in 35 mL liquid media (SB55 or SBP6) on a rotary shaker, 150 rpm, at 28°C with mixed florescent and incandescent lights on a 16:8 h day/night schedule. Cultures were subcultured every four weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

Soybean embryogenic suspension cultures were transformed with pCS3FdST1R by the method of particle gun bombardment (see Kline et al. (1987) Nature (London) 327:70). A Du Pont Biolistic PDS1000/HE instrument (helium retrofit) was used for these transformations.

To 50 mL of a 60 mg/mL 1 mm gold particle suspension was added (in order); 5 µL DNA(1 µg/µL), 20 µL spermidine (0.1M), and 50 µl $CaCl_2$ (2.5 M). The particle preparation was agitated for 3 min, spun in a microfuge for 10 sec and the supernatant removed. The DNA-coated particles were then washed once in 400 µL 70% ethanol and resuspended in 40 µL of anhydrous ethanol. The DNA/particle suspension was sonicated three times

for 1 sec each. Five µL of the DNA-coated gold particles w re then loaded on each macro carrier disk.

Approximately 300-400 mg of a four week old suspension culture was placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue were normally bombarded. Membrane rupture pressure was set at 1000 psi and the chamber was evacuated to a vacuum of 28 inches of mercury. The tissue was placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the tissue was placed back into liquid and cultured as described above.

Eleven days post bombardment, the liquid media was exchanged with fresh SB55 containing 50 mg/mL hygromycin. The selective media was refreshed weekly. Seven weeks post bombardment, green, transformed tissue was observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue was removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Thus each new line was treated as independent transformation event. These suspensions can then be maintained as suspensions of embryos clustered in an immature developmental stage through subculture or regenerated into whole plants by maturation and germination of individual somatic embryos.

Transformed embryogenic clusters were removed from liquid culture and placed on a solid agar media (SB103) containing no hormones or antibiotics. Embryos were cultured for eight weeks at 26°C with mixed florescent and incandescent lights on a 16:8 h day/night schedule. During this period, individual embryos were removed from the clusters and analyzed at various stages of embryo

development After eight weeks th embryos become suitable for germination.

EXAMPLE 15

ANALYSIS OF TRANSGENIC GLYCINE MAX PLANTS

While in the globular embryo state in liquid culture as described in Example 14, somatic soybean embryos contain very low amounts of triacylglycerol or storage proteins typical of maturing, zygotic soybean embryos. At this developmental stage, the ratio of total triacylglyceride to total polar lipid (phospholipids and glycolipid) is about 1:4, as is typical of zygotic soybean embryos at the developmental

stage from which the somatic embryo culture was initiated. At the globular stage as well, the mRNAs for the prominant seed proteins (a' subunit of β-conglycinin, Kunitz Trypsin Inhibitor III and Soybean Seed Lectin) are essentially absent. Upon transfer to hormone free media to allow differentiation to the maturing somatic embryo state as described in Example 14, triacylglycerol becomes the most abundant lipid class. As well, mRNAs for a'-subunit of β-conglycinin, Kunitz Trypsin Inhibitor III and Soybean Seed Lectin become very abundant messages in the total mRNA population. In these respects the somatic soybean embryo system behaves very similarly to maturing zygotic soybean embryos <u>in vivo</u>, and is therefore a good and rapid model system for analyzing the phenotypic effects of modifying the expression of genes in the fatty acid biosynthesis pathway. Similar somatic embryo culture systems have been documented and used in another oilseed crop, rapeseed (Taylor et al. (1990) Planta 181:18-26). Fatty acid analysis was performed as described in Example 12 using single embryos as the tissue source. A number of embryos from line 2872 (control tissue transformed with pCST) and lines 299,303,306 and 307 (line 2872 transformed with plasmid pCS3FdST1R) were analyzed for fatty acid content. The relative fatty-acid composition of embryos taken from tissue transformed with pCS3FdST1R was compared with control tissue, transformed with pCST. The results of this analysis are shown in Table 12.

<u>TABLE 12</u>

	2	14.6	3.5	10.0	61.3	10.6
	3	18.7	2.6	6.8	53.0	19.0
307-1-7	1	15.3	3.5	12.5	60.3	8.5
	2	16.2	2.2	13.9	57.1	10.6
	3	14.9	3.1	12.2	58.0	11.8
307-1-9	1	16.4	2.9	23.2	47.9	9.6
	2	19.6	0.0	20.4	51.3	8.8
	3	16.8	3.3	24.6	49.6	5.7
307-1-11	1	18.1	3.6	5.7	52.9	19.7
	2	14.7	3.7	9.9	58.7	13.0
	3	15.1	3.7	11.3	55.8	14.1

The average 18:3 content of control embryos was 14.5% with a range from 11.1% to 18.0%. The average 18:3 content of transformed embryos was 11.5% with a range of 6.3% to 19.9%. Almost 80% of the transformed embryos (38/48) had an 18:3 content below that of the control mean. About 44% had an 18:3 content less than the lowest observed control value and 12.5% had an 18:3 content less than half of the control mean value (i.e., less than 7.5%). The lowest 18:3 content observed in transformed tissue was 6.3% (299-1-3, 307-1-2 #1) compared with the control low of 11.1%. In all cases in transformed tissue, a decrease in 18:3 content was reflected by an equivalent increase in 18:2 content indicating that the desaturation of 18:2 to 18:3 had

been reduced. The relative content of the the other fatty acids remained unchanged.

Southern analysis for the presence of the intact, introduced antisense construction was performed, as described in Example 12 using Bam HI cut gDNA, on a number of the transformed lines listed below using groups of embryos from a single transformation event. The approximate intact antisense copy number was estimated from the number and intensity of hybridizing bands on the autoradiograms and is shown in Table 13.

TABLE 13

Line No.	Antisense copy No.	18:3 (low)	18:3 (average)	18:2/18:3 ratio
2872	0	11.1	14.5	3.6
303-7/1	1	11.4	12.6	4.7
307-1/2	3	12.2	16.0	3.5
306-4/8	3	10.8	12.2	4.3
307-1/7	4	8.5	10.3	5.7
306-4/5	6	7.4	10.4	5.8
307-1/1	6	6.3	9.6	6.3
299-15/1	7	8.1	9.7	6.1
307-1/4	8	6.7	7.7	8.0

There was a reasonable correlation between intact antisense copy number and 18:3 content, an increase in copy number correlating with a decreased 18:3 content and a consequent increase in the 18:2/18:3 ratio. The average 18:2/18:3 ratio of line 307-1/4, which had at least 8 copies of the antisense cDNA, was more than twice that of the control.

(vii) PRIOR APPLICATION DATA:

(A) APPLICATION NUMBER: 07/804,259
(B) FILING DATE: 4 DECEMBER 1991

(viii) ATTORNEY/AGENT INFORMATION:

(A) NAME: Floyd, Linda A.
(B) REGISTRATION NUMBER: 33,692
(C) REFERENCE/DOCKET NUMBER: BB-1036-A

(ix) TELECOMMUNICATION INFORMATION:

(A) TELEPHONE: (302) 992-4929
(B) TELEFAX: (302) 892-7949
(C) TELEX: 835420

(2) INFORMATION FOR SEQ ID NO:1:

(i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 1350 base pairs
(B) TYPE: nucleic acid
(C) STRANDEDNESS: single
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(iii) HYPOTHETICAL: NO

(vi) ORIGINAL SOURCE:

(A) ORGANISM: Arabidopsis thaliana IMMEDIATE SOURCE:
(B) CLONE: pCF3

(ix) FEATURE:

(A) NAME/KEY: CDS
(B) LOCATION: 46..1206

CLAIMS

1. An isolated nucleic acid fragment comprising a nucleic acid sequence encoding a fatty acid desaturase or a fatty acid desaturase-related enzyme with an amino acid identity of 50% or greater to the polypeptide encoded by SEQ ID NOS:1, 4, 6, 8, 10, 12, 14 or 16.

2. The isolated nucleic acid fragment of Claim 1 wherein the amino acid identity is 65% or greater to the polypeptide encoded by SEQ ID NOS:1, 4, 6, 8, 10, 12, 14 or 16.

3. The isolated nucleic acid fragment of Claim 1 wherein the nucleic acid identity is 90% or greater to SEQ ID NOS:1, 4, 6, 8, 10, 12, 14 or 16.

4. An isolated nucleic acid fragment of Claim 1 wherein said fragment is isolated from a plant selected from the group consisting of soybean, oilseed *Brassica* species, *Arabidopsis thaliana* and corn.

5. A chimeric gene capable of causing altered levels of linolenic acid in a transformed plant cell, the gene comprising a nucleic acid fragment of any of Claims 1, 2, or 3, the fragment operably linked to suitable regulatory sequences.

6. Plants containing the chimeric genes of Claim 5.

7. Oil obtained from seeds of the plants containing the chimeric genes of Claim 5.

8. A method of producing seed oil containing altered levels of linolenic (18:3) acid comprising:

(a) transforming a plant cell of an oil-producing species with a chimeric gene of Claim 5;

(b) growing fertile plants from the transformed plant cells of step (a);

(c) screening progeny seeds from the fertile plants of step (b) for the desired levels of linolenic (18:3) acid; and

(d) processing the progeny seed of step (c) to obtain seed oil containing altered levels of linolenic (18:3) acid.

9 The product of the method of Claim 8.

10. A method of Claim 8 wherein said plant cell of an oil-producing species is selected from the group consisting of Arabidopsis thaliana, soybean, oilseed Brassica species, sunflower, cotton, cocoa, peanut, safflower, and corn.

11. A method of breeding plant species producing altered levels of linolenic acid in the seed oil of oil-producing plant species comprising:

(a) making a cross between two varieties of oil-producing species differing in the linolenic acid trait;

(b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and

(c) hybridizing the Southern blot with a radiolabelled nucleic acid fragment of Claim 1.

12. The product of the method of Claim 11.

13. A method of RFLP mapping in a genomic RFLP marker comprising:

(a) making a cross between two varieties of plants;

(b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and

(c) hybridizing the Southern blot with a radiolabelled nucleic acid fragments of Claim 1.

14. A method to isolate nucleic acid fragments encoding fatty acid desaturases and fatty acid desaturase-related enzymes, comprising:

(a) comparing SEQ ID NOS:2, 5, 7, 9, 11, 13, 15 and 17 with other fatty acid desaturase polypeptide sequences;

(b) identifying the conserved sequence(s) of 4 or more amino acids obtained in step (a);

(c) making region-specific nucleotide probe(s) or oligomer(s) based on the conserved sequences identified in step b; and

(d) using the nucleotide probe(s) or oligomers(s) of step c to isolate sequences encoding fatty acid desaturases and fatty-acid desaturase-related enzymes by sequence-dependent protocols.

15. The product of the method of Claim 14.

16. The isolated genomic DNA of Arabidopsis thaliana identified by accession number ATCC 75167.

17. An isolated cDNA clone which encodes for soybean delta-15 desaturase, the clone designated pXF1 comprising the DNA sequence of SEQ ID NO 10 and identified by accession number ATCC 68874.

18. An isolated cDNA clone which encodes for oilseed Brassica species delta-15 desaturase, the clone designated pBNSF3 comprising the DNA sequence of SEQ ID NO:6 and identified by accession number ATCC 68854.

19. An isolated Polymerase Chain Reaction Product for Zea mays delta-15 desaturase, the clone designated pcr20 comprising the DNA sequence of SEQ ID NO:14.

INTERNATIONAL SEARCH REPORT

International Application No ?CT/US 92/10284

I. CLASSIFICATION OF SUBJECT MATTER (if several classification symbols apply, indicate all)[6]
According to International Patent Classification (IPC) or to both National Classification and IPC
Int.Cl. 5 C12N15/53; C12N15/82; C11B1/00; C12Q1/68

II. FIELDS SEARCHED

Minimum Documentation Searched[7]

Classification System	Classification Symbols

° Special categories of cited documents : [10]

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

ANNEX TO THE INTERNATIONAL SEARCH REPORT ON INTERNATIONAL PATENT APPLICATION NO.

US 9210284
SA 67975

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report.
The members are as contained in the European Patent Office EDP file on 17/03/93
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.

(54) Title: GENES FOR MICROSOMAL DELTA-12 FATTY ACID DESATURASES AND RELATED ENZYMES FROM PLANTS

(57) Abstract

The preparation and use of nucleic acid fragments encoding fatty acid desaturase enzymes are described. The invention permits alteration of plant lipid composition. Chimeric genes incorporating such nucleic acid fragments with suitable regulatory sequences may be used to create transgenic plants with altered levels of unsaturated fatty acids.

TITLE

GENES FOR MICROSOMAL DELTA-12 FATTY ACID DESATURASES AND RELATED ENZYMES FROM PLANTS

FIELD OF THE INVENTION

The invention relates to the preparation and use of nucleic acid fragments encoding fatty acid desaturase enzymes to modify plant lipid composition. Chimeric genes incorporating such nucleic acid fragments and suitable regulatory sequences may be used to create transgenic plants with altered levels of unsaturated fatty acids.

BACKGROUND OF THE INVENTION

Plant lipids have a variety of industrial and nutritional uses and are central to plant membrane function and climatic adaptation. These lipids represent a vast array of chemical structures, and these structures determine the physiological and industrial properties of the lipid. Many of these structures result either directly or indirectly from metabolic processes that alter the degree of unsaturation of the lipid. Different metabolic regimes in different plants produce these altered lipids, and either domestication of exotic plant species or modification of agronomically adapted species is usually required to economically produce large amounts of the desired lipid.

Plant lipids find their major use as edible oils in the form of triacylglycerols. The specific performance and health attributes of edible oils are determined largely by their fatty acid composition. Most vegetable oils derived from commercial plant varieties are composed primarily of palmitic (16:0), stearic (18:0), oleic (18:1), linoleic (18:2) and linolenic (18:3) acids. Palmitic and stearic acids are, respectively, 16- and 18-carbon-long, saturated fatty acids. Oleic, linoleic, and linolenic acids are 18-carbon-long,

unsaturated fatty acids containing one, two, and three double bonds, respectively. Oleic acid is referred to as a mono-unsaturated fatty acid, while linoleic and linolenic acids are referred to as poly-unsaturated fatty acids. The relative amounts of saturated and unsaturated fatty acids in commonly used, edible vegetable oils are summarized below (Table 1):

TABLE 1

Percentages of Saturated and Unsaturated Fatty Acids in the Oils of Selected Oil Crops

	Saturated	Mono-unsaturated	Poly-unsaturated
Canola	6%	58%	36%
Soybean	15%	24%	61%
Corn	13%	25%	62%
Peanut	18%	48%	34%
Safflower	9%	13%	78%
Sunflower	9%	41%	51%
Cotton	30%	19%	51%

Many recent research efforts have examined the role that saturated and unsaturated fatty acids play in reducing the risk of coronary heart disease. In the past, it was believed that mono-unsaturates, in contrast to saturates and poly-unsaturates, had no effect on serum cholesterol and coronary heart disease risk. Several recent human clinical studies suggest that diets high in mono-unsaturated fat and low in saturated fat may reduce the "bad" (low-density lipoprotein) cholesterol while maintaining the "good" (high-density lipoprotein) cholesterol (Mattson et al., Journal of Lipid Research (1985) 26:194-202).

A vegetable oil low in total saturates and high in mono-unsaturates would provide significant health

benefits to consumers as well as economic benefits to oil processors. As an example, canola oil is considered a very healthy oil. However, in use, the high level of poly-unsaturated fatty acids in canola oil renders the oil unstable, easily oxidized, and susceptible to development of disagreeable odors and flavors (Gailliard, 1980, Vol. 4, pp. 85-116 In: Stumpf, P. K., Ed., The Biochemistry of Plants, Academic Press, New York). The levels of poly-unsaturates may be reduced by hydrogenation, but the expense of this process and the concomitant production of nutritionally questionable trans isomers of the remaining unsaturated fatty acids reduces the overall desirability of the hydrogenated oil (Mensink et al., New England J. Medicine (1990) N323: 439-445). Similar problems exist with soybean and corn oils.

For specialized uses, high levels of poly-unsaturates can be desirable. Linoleate and linolenate are essential fatty acids in human diets, and an edible oil high in these fatty acids can be used for nutritional supplements, for example in baby foods.

Mutation-breeding programs have met with some success in altering the levels of poly-unsaturated fatty acid levels found in the edible oils of agronomic species. Examples of commercially grown varieties are high (85%) oleic sunflower and low (2%) linolenic flax (Knowles, (1980) pp. 35-38 In: Applewhite, T. H., Ed., World Conference on Biotechnology for the Fats and Oils Industry Proceedings, American Oil Chemists' Society). Similar commercial progress with the other plants shown in Table 1 has been largely elusive due to the difficult nature of the procedure and the pleiotropic effects of the mutational regime on plant hardiness and yield potential.

The biosynthesis of the major plant lipids has been the focus of much research (Browse et al., Ann. Rev. Plant Physiol. Mol. Biol. (1991) 42:467-506). These studies show that, with the notable exception of the soluble stearoyl-acyl carrier protein desaturase, the controlling steps in the production of unsaturated fatty acids are largely catalyzed by membrane-associated fatty acid desaturases. Desaturation reactions occur in plastids and in the endoplasmic reticulum using a variety of substrates including galactolipids, sulfolipids, and phospholipids. Genetic and physiological analyses of Arabidopsis thaliana nuclear mutants defective in various fatty acid desaturation reactions indicates that most of these reactions are catalyzed by enzymes encoded at single genetic loci in the plant. The analyses show further that the different defects in fatty acid desaturation can have profound and different effects on the ultra-structural morphology, cold sensitivity, and photosynthetic capacity of the plants (Ohlrogge, et al., Biochim. Biophys. Acta (1991) 1082:1-26). However, biochemical characterization of the desaturase reactions has been meager. The instability of the enzymes and the intractability of their proper assay has largely limited researchers to investigations of enzyme activities in crude membrane preparations. These investigations have, however, demonstrated the role of delta-12 desaturase and delta-15 desaturase activities in the production of linoleate and linolenate from 2-oleoyl-phosphatidylcholine and 2-linoleoyl-phosphatidylcholine, respectively (Wang et al., Plant Physiol. Biochem. (1988) 26:777-792). Thus, modification of the activities of these enzymes represents an attractive target for altering the levels of lipid unsaturation by genetic engineering.

Nucleotide sequences encoding microsomal delta-9 stearoyl-coenzyme-A desaturases from yeast, rat, and mice have been described (Stukey, et al., J. Biol. Chem.(1990) 265:20144-20149; Thiede, et al., J. Biol. Chem. (1986) 261:13230-13235; Kaestner, et al., J. Biol. Chem. (1989) 264:14755-1476). Nucleotide sequences encoding soluble delta-9 stearoyl-acyl carrier protein desaturases from higher plants have also been described (Thompson, et al., Proc. Natl. Acad. Sci. U.S.A. (1991) 88:2578-2582; Shanklin et al., Proc. Natl. Acad. Sci. USA (1991) 88:2510-2514). A nucleotide sequence from coriander plant encoding a soluble fatty acid desaturase, whose deduced amino acid sequence is highly identical to that of the stearoyl-acyl carrier protein desaturase and which is responsible for introducing the double bond in petroselinic fatty acid (18:1, 6c), has also been described [Cahoon, et. al. (1992) Proc. Natl. Acad. Sci. U.S.A. 89:11184-11188]. Two fatty acid desaturase genes from the cyanobacterium, Synechocystis PCC6803, have been described: one encodes a fatty acid desaturase, designated *des A*, that catalyzes the conversion of oleic acid at the sn-1 position of galactolipids to linoleic acid [Wada, et al., Nature (1990) 347:200-203]; another encodes a delta-6 fatty acid desaturase that catalyzes the conversion of linoleic acid at the sn-1 position of galactolipids to γ-linolenic acid (18:2, 6c,9c) [WO 9306712]. Nucleotide sequences encoding higher plant membrane-bound microsomal and plastid delta-15 fatty acid desaturases have also been described [WO 9311245]; Arondel, V. et. al. (1992) Science 258:1353-1355]. There is no report of the isolation of higher plant genes encoding fatty acid desaturases other than the soluble delta-6 and delta-9 desaturases and the membrane-bound (microsomal and plastid) delta-15 desaturases. While there is

extensive amino acid sequence identity between the soluble desaturases and significant amino acid sequence identity between the higher plant microsomal and plastid delta-15 desaturases, there is no significant homology between the soluble and the membrane-bound desaturases. Sequence-dependent protocols based on the sequences encoding delta-15 desaturases have been unsuccessful in cloning sequences for microsomal delta-12 desaturase. For example, nucleotide sequences of microsomal or plastid delta-15 desaturases as hybridization probes have been unsuccessful in isolating a plant microsomal delta-12 desaturase clone. Furthermore, while we have used a set of degenerate oligomers made to a stretch of 12 amino acids, which is identical in all plant delta-15 desaturases and highly conserved (10/12) in the cyanobacterial *des A* desaturase, as a hybridization probe to isolate a higher plant nucleotide sequence encoding plastid delta-12 fatty acid desaturase, this method has been unsuccessful in isolating the microsomal delta-12 desaturase cDNAs. Furthermore, there has been no success in isolating the microsomal delta-12 desaturase by using the polymerase chain reaction products derived from plant DNA, plant RNA or plant cDNA library using PCR primers made to stretches of amino acids that are conserved between the higher plant delta-15 and *des A* desaturases. Thus, there are no teachings which enable the isolation of plant microsomal delta-12 fatty acid desaturases or plant fatty acid desaturase-related enzymes. Furthermore, there is no evidence for a method to control the the level of delta-12 fatty acid desaturation or hydroxlylation in plants using nucleic acids encoding delta-12 fatty acid desaturases or hydroxylases.

The biosynthesis of the minor plant lipids has been less well studied. While hundreds of different fatty

acids have been found, many from the plant kingdom, only a tiny fraction of all plants have been surveyed for their lipid content (Gunstone, et al., Eds., (1986) The Lipids Handbook, Chapman and Hall Ltd., Cambridge). Accordingly, little is known about the biosynthesis of these unusual fatty acids and fatty acid derivatives. Interesting chemical features found in such fatty acids include, for example, allenic and conjugated double bonds, acetylenic bonds, trans double bonds, multiple double bonds, and single double bonds in a wide number of positions and configurations along the fatty acid chain. Similarly, many of the structural modifications found in unusual lipids (e.g., hydroxylation, epoxidation, cyclization, etc.) are probably produced via further metabolism following chemical activation of the fatty acid by desaturation or they involve a chemical reaction that is mechanistically similar to desaturation. Many of these fatty acids and derivatives having such features within their structure could prove commercially useful if an agronomically viable species could be induced to synthesize them by introduction of a gene encoding the appropriate desaturase. Of particular interest are vegetable oils rich in 12-hydroxyoctadeca-9-enoic acid (ricinoleic acid). Ricinoleic acid and its derivatives are widely used in the manufacture of lubricants, polymers, cosmetics, coatings and pharmaceuticals (e.g., see Gunstone, et al., Eds., (1986) The Lipids Handbook, Chapman and Hall Ltd., Cambridge). The only commercial source of ricinoleic acid is castor oil and 100% of the castor oil used by the U.S. is derived from beans grown elsewhere in the world, mainly Brazil. Ricinoleic acid in castor beans is synthesized by the addition of an hydroxyl group at the delta-12 position of oleic acid (Galliard & Stumpf (1966) J. Biol. Chem. 241: 5806-5812). This reaction

resembles the initial reaction in a possible mechanism for the desaturation of oleate at the delta-12 position to linoleate since dehydration of 12-hydroxyoctadeca-9-enoic acid, by an enzyme activity analogous to the hydroxydecanoyl dehydrase of E. coli (Cronan et al. (1988) J. Biol. Chem. 263:4641-4646), would result in the formation of linoleic acid. Evidence for the hydroxylation reaction being part of a general mechanism of enzyme-catalyzed desaturation in eukaryotes has been obtained by substituting a sulfur atom in the place of carbon at the delta-9 position of stearic acid. When incubated with yeast cell extracts the thiostearate was converted to a 9-sulfoxide (Buist et al. (1987) Tetrahedron Letters 28:857-860). This sulfoxidation was specific for sulfur at the delta-9 position and did not occur in a yeast delta-9-desaturase deficient mutant (Buist & Marecak (1991) Tetrahedron Letters 32:891-894). The 9-sulfoxide is the sulfur analogue of 9-hydroxyoctadecastearate, the proposed intermediate of stearate desaturation.

Hydroxylation of oleic acid to ricinoleic acid in castor bean cells, like microsomal desaturation of oleate in plants, occurs at the delta-12 position of the fatty acid at the sn-2 position of phosphatidylcholine in microsomes (Bafor et al. (1991) Plant Physiol 280:507-514). Furthermore, castor oleate delta-12 hydroxylation and plant oleate microsomal delta-12 desaturation are both inhibited by iron chelators and require molecular oxygen [Moreau & Stumpf (1981) Plant Physiology 67:672-676; Somerville, C. (1992) MSU-DOE Plant Research Laboratory Annual Report]. These biochemical similarities in conjunction with the observation that antibodies raised against cytochrome b_5 completely inhibit the activities of both oleate delta-12 desaturation in safflower microsomes and oleate

delta-12 hydroxylase in castor microsomes [Somerville, C. (1992) MSU-DOE Plant Research Laboratory Annual Report] comprise strong evidence that the hydroxylase and the desaturase are functionally related. It seems reasonable to assume, therefore, that the nucleotide sequence encoding a plant delta-12 desaturase would be useful in cloning the oleate hydroxylase gene from castor by sequence-dependent protocols. For example, by screening a castor DNA library with oligomers based on amino acid regions conserved between delta-12 desaturases, or regions conserved between delta-12 and other desaturases, or with oligomers based on amino acids conserved between delta-12 desaturases and known membrane-associated hydroxylases. It would be more efficient to isolate the castor oleate hydroxylase cDNA by combining the sequence dependent protocols with a "differential" library approach. One example of such a difference library would be based on different stages of castor seed development, since ricinoleic acid is not synthesized by very young castor seeds (less than 12 DAP, corresponding to stage I and stage II seeds in the scheme of Greenwood & Bewley, Can. J. Bot. (1982) 60:1751-1760), in the 20 days following these early stages the relative ricinoleate content increases from 0% to almost 90% of total seed fatty acids (James et al. Biochem. J. (1965) 95:448-452, Canvin. Can. J. Biochem. Physiol. (1963) 41:1879-1885). Thus it would be possible to make a cDNA "difference" library made from mRNA present in a stage when ricinoleic acid was being synthesized at a high rate but from which mRNA present in earlier stages was removed. For the earlier stage mRNA, a stage such as stage II (10 DAP) when ricinoleic acid is not being made but when other unsaturated fatty acids are, would be appropriate. The construction of libraries containing only differentially expressed genes

is well known in the art (Sargent. Meth. Enzymol. (1987) 152:423-432). Assembly of the free ricinoleic acid, via ricinoleoyl-CoA, into triacylglycerol is readily catalyzed by canola and safflower seed microsomes (Bafor et al., Biochem J. (1991) 280:507-514, Wiberg et al. 10th International Symposium on the Metabolism, Strucure & Function of Plant Lipids (1992), Jerba, Tunisia) and ricinoleic acid is removed from phosphatidylcholine by a lipase common to all oilseeds investigated. Thus, expression of the castor bean oleate hydroxylase gene in oil crops, such as canola seeds and soybeans, would be expected to result in an oil rich in triglycerides containing ricinoleic acid.

SUMMARY OF THE INVENTION

Applicants have discovered a means to control the nature and levels of unsaturated fatty acids in plants. Nucleic acid fragments from cDNAs or genes encoding fatty acid desaturases are used to create chimeric genes. The chimeric genes may be used to transform various plants to modify the fatty acid composition of the plant or the oil produced by the plant. More specifically, one embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a fatty acid desaturase or a fatty acid desaturase-related enzyme with an amino acid identity of 50%, 60%, 90% or greater respectively to the polypeptide encoded by SEQ ID NOS:1, 3, 5, 7, 9, 11, or 15. Most specifically, the invention pertains to a gene sequence for plant microsomal delta-12 fatty acid desaturase or desaturase-related enzyme. The plant in this embodiment may more specifically be soybean, oilseed *Brassica* species, *Arabidopsis thaliana*, castor, and corn.

Another embodiment of this invention involves the use of these nucleic acid fragments in sequence-

dependent protocols. Examples include use of the fragments as hybridization probes to isolate nucleotide sequences encoding other fatty acid desaturases or fatty acid desaturase-related enzymes. A related embodiment involves using the disclosed sequences for amplification of RNA or DNA fragments encoding other fatty acid desaturases or fatty acid desaturase-related enzymes.

Another aspect of this invention involves chimeric genes capable of modifying the fatty acid composition in the seed of a transformed plant, the gene comprising nucleic acid fragments related as defined to SEQ ID NOS:1, 3, 5, 7, 9, or 15 encoding fatty acid desaturases or SEQ ID NOS:11 encoding a desaturase or desaturase-related enzyme operably-linked in suitable orientation to suitable regulatory sequences. Preferred are those chimeric genes which incorporate nucleic acid fragments encoding microsomal delta-12 fatty acid desaturase or desaturase-related enzymes.

Yet another embodiment of the invention involves a method of producing seed oil containing altered levels of unsaturated fatty acids comprising: (a) transforming a plant cell with a chimeric gene described above; (b) growing sexually mature plants from the transformed plant cells of step (a); (c) screening progeny seeds from the sexually mature plants of step (b) for the desired levels of unsaturated fatty acids, and (d) processing the progeny seed of step (c) to obtain seed oil containing altered levels of the unsaturated fatty acids. Preferred plant cells and oils are derived from soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, coconut, flax, oil palm, and corn. Preferred methods of transforming such plant cells would include the use of Ti and Ri plasmids of Agrobacterium, electroporation, and high-velocity ballistic bombardment.

The invention also is embodied in a method of RFLP bre ding to obtain altered levels of oleic acids in the seed oil of oil producing plant species. This method involves (a) making a cross between two varieties of oil producing plant species differing in the oleic acid trait; (b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross; and (c) hybridizing the Southern blot with the radiolabelled nucleic acid fragments encoding the fatty acid desaturases or desaturase-related enzymes.

The invention is also embodied in a method of RFLP mapping that uses the isolated microsomal delta-12 desaturase cDNA or related genomic fragments described herein.

The invention is also embodied in plants capable of producing altered levels of fatty acid desaturase by virtue of containing the chimeric genes described herein. Further, the invention is embodied by seed oil obtained from such plants.

BRIEF DESCRIPTION OF THE SEQUENCE DESCRIPTIONS

The invention can be more fully understood from the following detailed description and the Sequence Descriptions which form a part of this application. The Sequence Descriptions contain the three letter codes for amino acids as defined in 37 C.F.R. 1.822 which are incorporated herein by reference.

SEQ ID NO:1 shows the 5' to 3' nucleotide sequence of 1372 base pairs of the *Arabidopsis thaliana* cDNA which encodes microsomal delta-12 desaturase. Nucleotides 93-95 and nucleotides 1242-1244 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 93-1244). Nucleotides 1-92 and 1245-1372 are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:2 is the 383 amino acid protein sequence deduced from the open reading frame (nucleotides 93-1244 in SEQ ID NO:1.

SEQ ID NO:3 shows the 5' to 3' nucleotide sequence of 1394 base pairs of the Brassica napus cDNA which encodes microsomal delta-12 desaturase in plasmid pCF2-165d. Nucleotides 99 to 101 and nucleotides 1248 to 1250 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 99 to 1250). Nucleotides 1 to 98 and 1251 to 1394 are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:4 is the 383 amino acid protein sequence deduced from the open reading frame (nucleotides 99 to 1250) in SEQ ID NO:3.

SEQ ID NO:5 shows the 5' to 3' nucleotide sequence of 1369 base pairs of soybean (Glycine max) cDNA which encodes microsomal delta-12 desaturase in plasmid pSF2-169K. Nucleotides 108 to 110 and nucleotides 1245 to 1247 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 108 to 1247). Nucleotides 1 to 107 and 1248 to 1369 are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:6 is the 381 amino acid protein sequence deduced from the open reading frame (nucleotides 113 to 1258) in SEQ ID NO:5.

SEQ ID NO:7 shows the 5' to 3' nucleotide sequence of 1790 base pairs of corn (Zea mays) cDNA which encodes microsomal delta-12 desaturase in plasmid pFad2#1. Nucleotides 165 to 167 and nucleotides 1326 to 1328 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 164 to 1328). Nucleotides 1 to 163 and 1329 to 1790

are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:8 is the 387 amino acid protein sequence deduced from the open reading frame (nucleotides 164 to 1328) in SEQ ID NO:7.

SEQ ID NO:9 shows the 5' to 3' nucleotide sequence of 673 base pairs of castor (Ricinus communis) incomplete cDNA which encodes part of a microsomal delta-12 desaturase in plasmid pRF2-1C. The sequence encodes an open reading frame from base 1 to base 673.

SEQ ID NO:10 is the 219 amino acid protein sequence deduced from the open reading frame (nucleotides 1 to 657) in SEQ ID NO:9.

SEQ ID NO:11 shows the 5' to 3' nucleotide sequence of 1369 base pairs of castor (Ricinus communis) cDNA which encodes part of a microsomal delta-12 desaturase or desaturase-related enzyme in plasmid pRF197C-42. Nucleotides 184 to 186 and nucleotides 1340 to 1342 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 184 to 1347). Nucleotides 1 to 183 and 1348 to 1369 are, respectively, the 5' and 3' untranslated nucleotides.

SEQ ID NO:12 is the 387 amino acid protein sequence deduced from the open reading frame (nucleotides 184 to 1342) in SEQ ID NO:11.

SEQ ID NO:13 is the sequence of a set of 64-fold degenerate 26 nucleotide-long oligomers, designated NS3, made to conserved amino acids 101-109 of SEQ ID NO:2, designed to be used as sense primers in PCR to isolate novel sequences encoding microsomal delta-12 desaturases or desaturase-like enzymes.

SEQ ID NO:14 is the sequence of a set of 64-fold degenerate and 26 nucleotide-long oligomers, designated NS9, which is made to conserved amino acids 313-321 of

SEQ ID NO:2 and designed to be used as antisense primers in PCR to isolate novel sequences encoding microsomal delta-12 desaturases or desaturase-like enzymes.

SEQ ID NO:15 shows the 5' to 3' nucleotide sequence of 2973 bp of Arabidopsis thaliana genomic fragment containing the microsomal delta-12 desaturase gene contained in plasmid pAGF2-6. Its nucleotides 433 and 2938 correspond to the start and end, respectively, of SEQ ID NO:1. Its nucleotides 521 to 1654 are the 1134 bp intron.

SEQ ID NO:16 is the sequence of a set of 256-fold degenerate and 25 nucleotide-long oligomers, designated RB5a, which is made to conserved amino acids 318-326 of SEQ ID NO:2 and designed to be used as antisense primers in PCR to isolate novel sequences encoding microsomal delta-12 desaturases or desaturase-like enzymes.

SEQ ID NO:17 is the sequence of a set of 128-fold degenerate and 25 nucleotide-long oligomers, designated RB5b, which is made to conserved amino acids 318-326 of SEQ ID NO:2 and designed to be used as antisense primers in PCR to isolate novel sequences encoding microsomal delta-12 desaturases or desaturase-like enzymes.

DETAILED DESCRIPTION OF THE INVENTION

Applicants have isolated nucleic acid fragments that encode plant fatty acid desaturases and that are useful in modifying fatty acid composition in oil-producing species by genetic transformation.

Thus, transfer of the nucleic acid fragments of the invention or a part thereof that encodes a functional enzyme, along with suitable regulatory sequences that direct the transcription of their mRNA, into a living cell will result in the production or over-production of plant fatty acid desaturases and will result in increased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transcription of their antisense RNA, into plants will result in the inhibition of expression of the endogenous fatty acid desaturase that is substantially homologous with the transferred nucleic acid fragment and will result in decreased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transcription of their mRNA, into plants may result in inhibition by cosuppression of the expression of the endogenous fatty acid desaturase gene that is substantially homologous with the transferred nucleic acid fragment and may result in decreased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

The nucleic acid fragments of the invention can also be used as restriction fragment length polymorphism (RFLP) markers in plant genetic mapping and plant breeding programs.

The nucleic acid fragments of the invention or oligomers derived therefrom can also be used to isolate other related fatty acid desaturase genes using DNA, RNA, or a library of cloned nucleotide sequences from the same or different species by well known sequence-dependent protocols, including, for example, methods of nucleic acid hybridization and amplification by the polymerase chain reaction.

Definitions

In the context of this disclosure, a number of terms shall be used. Fatty acids are specified by the number of carbon atoms and the number and position of the double bond: the numbers before and after the colon

refer to the chain l ngth and the number of double bonds, respectively. The number following the fatty acid designation indicates the position of the double bond from the carboxyl end of the fatty acid with the "c" affix for the *cis*-configuration of the double bond. For example, palmitic acid (16:0), stearic acid (18:0), oleic acid (18:1,9c), petroselinic acid (18:1, 6c), linoleic acid (18:2,9c,12c), γ-linolenic acid (18:3, 6c,9c,12c) and α-linolenic acid (18:3, 9c,12c,15c). Unless otherwise specified 18:1, 18:2 and 18:3 refer to oleic, linoleic and linolenic fatty acids. Ricinoleic acid refers to an 18 carbon fatty acid with a *cis*-9 double bond and a 12-hydroxyl group. The term "fatty acid desaturase" used herein refers to an enzyme which catalyzes the breakage of a carbon-hydrogen bond and the introduction of a carbon-carbon double bond into a fatty acid molecule. The fatty acid may be free or esterified to another molecule including, but not limited to, acyl-carrier protein, coenzyme A, sterols and the glycerol moiety of glycerolipids. The term "glycerolipid desaturases" used herein refers to a subset of the fatty acid desaturases that act on fatty acyl moieties esterified to a glycerol backbone. "Delta-12 desaturase" refers to a fatty acid desaturase that catalyzes the formation of a double bond between carbon positions 6 and 7 (numbered from the methyl end), (i.e., those that correspond to carbon positions 12 and 13 (numbered from the carbonyl carbon) of an 18 carbon-long fatty acyl chain. "Delta-15 desaturase" refers to a fatty acid desaturase that catalyzes the formation of a double bond between carbon positions 3 and 4 (numbered from the methyl end), (i.e., those that correspond to carbon positions 15 and 16 (numbered from the carbonyl carbon) of an 18 carbon-long fatty acyl chain. Examples of fatty acid desaturases include, but are not limited

to, the microsomal delta-12 and delta-15 desaturases that act on phosphatidylcholine lipid substrat s; the chloroplastic or plastid delta-12 and delta-15 desaturases that act on phosphatidyl glycerol and galactolipids; and other desaturases that act on such fatty acid substrates such as phospholipids, galacto-lipids, and sulfolipids. "Microsomal desaturase" refers to the cytoplasmic location of the enzyme, while "chloroplast desaturase" and "plastid desaturase" refer to the plastid location of the enzyme. These fatty acid desaturases may be found in a variety of organisms including, but not limited to, higher plants, diatoms, and various eukaryotic and prokaryotic microorganisms such as fungi and photosynthetic bacteria and algae. The term "homologous fatty acid desaturases" refers to fatty acid desaturases that catalyze the same desaturation on the same lipid substrate. Thus, microsomal delta-15 desaturases, even from different plant species, are homologous fatty acid desaturases. The term "heterologous fatty acid desaturases" refers to fatty acid desaturases that catalyze desaturations at different positions and/or on different lipid substrates. Thus, for example, microsomal delta-12 and delta-15 desaturases, which act on phosphatidylcholine lipids, are heterologous fatty acid desaturases, even when from the same plant. Similarly, microsomal delta-15 desaturase, which acts on phosphatidylcholine lipids, and chloroplast delta-15 desaturase, which acts on galactolipids, are heterologous fatty acid desaturases, even when from the same plant. It should be noted that these fatty acid desaturases have never been isolated and characterized as proteins. Accordingly, the terms such as "delta-12 desaturase" and "delta-15 desaturase" are used as a convenience to describe the proteins encoded by nucleic acid fragments

that have been isolated based on the phenotypic effects caused by their disruption. They do not imply any catalytic mechanism. For example, delta-12 desaturase refers to the enzyme that catalyzes the formation of a double bond between carbons 12 and 13 of an 18 carbon fatty acid irrespective of whether it "counts" the carbons from the methyl, carboxyl end, or the first double bond. The term "fatty acid desaturase-related enzyme" refers to enzymes whose catalytic product may not be a carbon-carbon double bond but whose mechanism of action is similar to that of a fatty acid desaturase (that is, catalysis of the displacement of a carbon-hydrogen bond of a fatty acid chain to form a fatty-hydroxyacyl intermediate or end-product). Examples include delta-12 hydroxylase which means a delta-12 fatty acid hydroxylase or the oleate hydroxylase responsible for the synthesis of ricinoleic acid from oleic acid.

The term "nucleic acid" refers to a large molecule which can be single-stranded or double-stranded, composed of monomers (nucleotides) containing a sugar, a phosphate and either a purine or pyrimidine. A "nucleic acid fragment" is a fraction of a given nucleic acid molecule. In higher plants, deoxyribonucleic acid (DNA) is the genetic material while ribonucleic acid (RNA) is involved in the transfer of the information in DNA into proteins. A "genome" is the entire body of genetic material contained in each cell of an organism. The term "nucleotide sequence" refers to the sequence of DNA or RNA polymers, which can be single- or double-stranded, optionally containing synthetic, non-natural or altered nucleotide bases capable of incorporation into DNA or RNA polymers. The term "oligomer" refers to short nucleotide sequences, usually up to 100 bases long. As used herein, the term "homologous to" refers

to the relatedness between the nucleotide sequence of two nucleic acid molecules or between the amino acid sequences of two protein molecules. Estimates of such homology are provided by either DNA-DNA or DNA-RNA hybridization under conditions of stringency as is well understood by those skilled in the art (Hames and Higgins, Eds. (1985) Nucleic Acid Hybridisation, IRL Press, Oxford, U.K.); or by the comparison of sequence similarity between two nucleic acids or proteins, such as by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453). As used herein, "substantially homologous" refers to nucleotide sequences that have more than 90% overall identity at the nucleotide level with the coding region of the claimed sequence, such as genes and pseudo-genes corresponding to the coding regions. The nucleic acid fragments described herein include molecules which comprise possible variations, both man-made and natural, such as but not limited to (a) those that involve base changes that do not cause a change in an encoded amino acid, or (b) which involve base changes that alter an amino acid but do not affect the functional properties of the protein encoded by the DNA sequence, (c) those derived from deletions, rearrangements, amplifications, random or controlled mutagenesis of the nucleic acid fragment, and (d) even occasional nucleotide sequencing errors.

"Gene" refers to a nucleic acid fragment that expresses a specific protein, including regulatory sequences preceding (5' non-coding) and following (3' non-coding) the coding region. "Fatty acid desaturase gene" refers to a nucleic acid fragment that expresses a protein with fatty acid desaturase activity. "Native" gene refers to an isolated gene with its own regulatory sequences as found in nature. "Chimeric gene" refers to a gene that comprises heterogeneous regulatory and

coding sequences not found in nature. "Endogenous" gene refers to the native gen normally found in its natural location in the genome and is not isolated. A "foreign" gene refers to a gene not normally found in the host organism but that is introduced by gene transfer. "Pseudo-gene" refers to a genomic nucleotide sequence that does not encode a functional enzyme.

"Coding sequence" refers to a DNA sequence that codes for a specific protein and excludes the non-coding sequences. It may constitute an "uninterrupted coding sequence", i.e., lacking an intron or it may include one or more introns bounded by appropriate splice junctions. An "intron" is a nucleotide sequence that is transcribed in the primary transcript but that is removed through cleavage and re-ligation of the RNA within the cell to create the mature mRNA that can be translated into a protein.

"Initiation codon" and "termination codon" refer to a unit of three adjacent nucleotides in a coding sequence that specifies initiation and chain termination, respectively, of protein synthesis (mRNA translation). "Open reading frame" refers to the coding sequence uninterrupted by introns between initiation and termination codons that encodes an amino acid sequence.

"RNA transcript" refers to the product resulting from RNA polymerase-catalyzed transcription of a DNA sequence. When the RNA transcript is a perfect complementary copy of the DNA sequence, it is referred to as the primary transcript or it may be a RNA sequence derived from posttranscriptional processing of the primary transcript and is referred to as the mature RNA. "Messenger RNA (mRNA)" refers to the RNA that is without introns and that can be translated into protein by the cell. "cDNA" refers to a double-stranded DNA that is complementary to and derived from mRNA. "Sense" RNA

refers to RNA transcript that includes the mRNA. "Antisense RNA" refers to a RNA transcript that is complementary to all or part of a target primary transcript or mRNA and that blocks the expression of a target gene by interfering with the processing, transport and/or translation of its primary transcript or mRNA. The complementarity of an antisense RNA may be with any part of the specific gene transcript, i.e., at the 5' non-coding sequence, 3' non-coding sequence, introns, or the coding sequence. In addition, as used herein, antisense RNA may contain regions of ribozyme sequences that increase the efficacy of antisense RNA to block gene expression. "Ribozyme" refers to a catalytic RNA and includes sequence-specific endoribonucleases.

As used herein, "suitable regulatory sequences" refer to nucleotide sequences in native or chimeric genes that are located upstream (5'), within, and/or downstream (3') to the nucleic acid fragments of the invention, which control the expression of the nucleic acid fragments of the invention. The term "expression", as used herein, refers to the transcription and stable accumulation of the sense (mRNA) or the antisense RNA derived from the nucleic acid fragment(s) of the invention that, in conjunction with the protein apparatus of the cell, results in altered levels of the fatty acid desaturase(s). Expression or overexpression of the gene involves transcription of the gene and translation of the mRNA into precursor or mature fatty acid desaturase proteins. "Antisense inhibition" refers to the production of antisense RNA transcripts capable of preventing the expression of the target protein. "Overexpression" refers to the production of a gene product in transgenic organisms that exceeds levels of production in normal or non-transformed organisms. "Cosuppression" refers to the expression of a foreign

gene which has substantial homology to an endog nous gene resulting in the suppression of expression of both the foreign and the endogenous gene. "Altered levels" refers to the production of gene product(s) in transgenic organisms in amounts or proportions that differ from that of normal or non-transformed organisms.

"Promoter" refers to a DNA sequence in a gene, usually upstream (5') to its coding sequence, which controls the expression of the coding sequence by providing the recognition for RNA polymerase and other factors required for proper transcription. In artificial DNA constructs promoters can also be used to transcribe antisense RNA. Promoters may also contain DNA sequences that are involved in the binding of protein factors which control the effectiveness of transcription initiation in response to physiological or developmental conditions. It may also contain enhancer elements. An "enhancer" is a DNA sequence which can stimulate promoter activity. It may be an innate element of the promoter or a heterologous element inserted to enhance the level and/or tissue-specificity of a promoter. "Constitutive promoters" refers to those that direct gene expression in all tissues and at all times. "Tissue-specific" or "development-specific" promoters as referred to herein are those that direct gene expression almost exclusively in specific tissues, such as leaves or seeds, or at specific development stages in a tissue, such as in early or late embryogenesis, respectively.

The "3' non-coding sequences" refers to the DNA sequence portion of a gene that contains a polyadenylation signal and any other regulatory signal capable of affecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by

affecting the addition of polyadenylic acid tracts to the 3' end of the mRNA precursor.

"Transformation" herein refers to the transfer of a foreign gene into the genome of a host organism and its genetically stable inheritance. "Restriction fragment length polymorphism" (RFLP) refers to different sized restriction fragment lengths due to altered nucleotide sequences in or around variant forms of genes. "Molecular breeding" refers to the use of DNA-based diagnostics, such as RFLP, RAPDs, and PCR in breeding. "Fertile" refers to plants that are able to propagate sexually.

"Plants" refer to photosynthetic organisms, both eukaryotic and prokaryotic, whereas the term "Higher plants" refers to eukaryotic plants. "Oil-producing species" herein refers to plant species which produce and store triacylglycerol in specific organs, primarily in seeds. Such species include soybean (Glycine max), rapeseed and canola (including Brassica napus, B. campestris), sunflower (Helianthus annus), cotton (Gossypium hirsutum), corn (Zea mays), cocoa (Theobroma cacao), safflower (Carthamus tinctorius), oil palm (Elaeis guineensis), coconut palm (Cocos nucifera), flax (Linum usitatissimum), castor (Ricinus communis) and peanut (Arachis hypogaea). The group also includes non-agronomic species which are useful in developing appropriate expression vectors such as tobacco, rapid cycling Brassica species, and Arabidopsis thaliana, and wild species which may be a source of unique fatty acids.

"Sequence-dependent protocols" refer to techniques that rely on a nucleotide sequence for their utility. Examples of sequence-dependent protocols include, but are not limited to, the methods of nucleic acid and oligomer hybridization and methods of DNA and RNA

amplification such as are exemplified in various uses of the polymerase chain reaction (PCR).

Various solutions used in the experimental manipulations are referred to by their common names such as "SSC", "SSPE", "Denhardt's solution", etc. The composition of these solutions may be found by reference to Appendix B of Sambrook, et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press).

T-DNA Mutagenesis and Identification of an Arabidopsis Mutant Defective in Microsomal Delta-12 Desaturation

In T-DNA mutagenesis (Feldmann, et al., Science (1989) 243:1351-1354), the integration of T-DNA in the genome can interrupt normal expression of the gene at or near the site of the integration. If the resultant mutant phenotype can be detected and shown genetically to be tightly linked to the T-DNA insertion, then the "tagged" mutant locus and its wild type counterpart can be readily isolated by molecular cloning by one skilled in the art.

Arabidopsis thaliana seeds were transformed by Agrobacterium tumefaciens C58C1rif strain harboring the avirulent Ti-plasmid pGV3850::pAK1003 that has the T-DNA region between the left and right T-DNA borders replaced by the origin of replication region and ampicillin resistance gene of plasmid pBR322, a bacterial kanamycin resistance gene, and a plant kanamycin resistance gene (Feldmann, et al., Mol. Gen. Genetics (1987) 208:1-9). Plants from the treated seeds were self-fertilized and the resultant progeny seeds, germinated in the presence of kanamycin, were self-fertilized to give rise to a population, designated T3, that was segregating for T-DNA insertions. T3 seeds from approximately 1700 T2 plants were germinated and grown under controlled

environment. One leaf from each of ten T3 plants of each line were pooled and analyzed for fatty acid composition. One line, designated 658, showed an incresed level of oleic acid (18:1). Analysis of twelve individual T3 seeds of line 658 identified two seeds that contained greater than 36% oleic acid while the remaining seeds contained 12-22% oleic acid. The mutant phenotype of increased level of oleic acid in leaf and seed tissues of line 658 and its segregation in individual T3 seeds suggested that line 658 harbors a mutation that affects desaturation of oleic acid to linoleic acid in both leaf and seed tissues. When approximately 200 T3 seeds of line 658 were tested for their ability to germinate in the presence of kanamycin, four kanamycin-sensitive seeds were identified, suggesting multiple, possibly three, T-DNA inserts in the original T2 line. When progeny seeds of 100 individual T3 plants were analyzed for fatty acid composition and their ability to germinate on kanamycin, one plant, designated 658-75, was identified whose progeny segregated 7 wild type:2 mutant for the increased oleic acid and 28 sensitive:60 resistant for kanamycin resistance. Approximately 400 T4 progeny seeds of derivative line 658-75 were grown and their leaves analyzed for fatty acid composition. Ninety one of these seedlings were identified as homozygous for the mutant (high oleic acid) phenotype. Eighty-three of these homozygous plants were tested for the presence of nopaline, another marker for T-DNA, and all of them were nopaline positive. On the basis of these genetic studies it was concluded that the mutation in microsomal delta-12 desaturation was linked to the T-DNA.

Isolation of Arabidopsis 658-75 Genomic DNA Containing the Disrupted Gene Controlling Microsomal Delta-12 Desaturation

In order to isolate the gene controlling microsomal delta-12 desaturation from wild-type *Arabidopsis*, a T-DNA-plant DNA "junction" fragment containing a T-DNA border integrated into the host plant DNA was isolated from the homozygous mutant plants of the 658-75 line of *Arabidopsis*. For this, genomic DNA from the mutant plant was isolated and completely digested by either Bam HI or Sal I restriction enzymes. In each case, one of the resultant fragments was expected to contain the origin of replication and ampicillin-resistance gene of pBR322 as well as the left T-DNA-plant DNA junction fragment. Such fragments were rescued as plasmids by ligating the digested genomic DNA fragments at a dilute concentration to facilitate self-ligation and then using the ligated fragments to transform *E. coli* cells. While no ampicillin-resistant colony was obtained from the plasmid rescue of Sal I-digested plant genomic DNA, a single ampicillin-resistant colony was obtained from the plasmid rescue of Bam HI-digested plant genomic DNA. The plasmid obtained from this transformant was designated p658-1. Restriction analysis of plasmid p658-1 with Bam HI, Sal I and Eco RI restriction enzymes strongly suggested that it contained the expected 14.2 kb portion of the T-DNA (containing pBR322 sequences) and a putative plant DNA/left T-DNA border fragment in a 1.6 kB Eco RI-Bam HI fragment. The 1.6 kb Eco RI-Bam HI fragment was subcloned into pBluescript SK [Stratagene] by standard cloning procedures described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press) and the resultant plasmid, designated pS1658.

Isolation of Microsomal Delta-12 Desaturase cDNA and Gene from Wild type Arabidopsis

The 1.6 kb Eco RI-Bam HI fragment, which contained the putative plant DNA flanking T-DNA, in plasmid p658-1 was isolated and used as a radiolabeled hybridization probe to screen a cDNA library made to polyA$^+$ mRNA from the above-ground parts of Arabidopsis thaliana plants, which varied in size from those that had just opened their primary leaves to plants which had bolted and were flowering [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735]. The cDNA inserts in the library were made into an Xho I site flanked by Eco RI sites in lambda Yes vector [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735]. Of the several positively-hybridizing plaques, four were subjected to plaque purification. Plasmids were excised from the purified phages by site-specific recombination using the cre-lox recombination system in E. coli strain BNN132 [Elledge et al. (1991) Proc. Natl. Acad Sci. USA 88:1731-1735]. The four excised plasmids were digested by Eco RI restriction enzyme and shown to contain cDNA inserts ranging in size between 1 kB and 1.5 kB. Partial nucleotide sequence determination and restriction enzyme mapping of all four cDNAs revealed their common identity.

The partial nucleotide sequences of two cDNAs, designated pSF2b and p92103, containing inserts of ca. 1.2 kB and ca. 1.4 kB, respectively, were determined. The composite sequence derived from these plasmids is shown as SEQ ID NO:1 and is expected to be contained completely in plasmid p92103. SEQ ID NO:1 shows the 5' to 3' nucleotide sequence of 1372 base pairs of the Arabidopsis cDNA which encodes microsomal delta-12 fatty acid desaturase. Nucleotides 93-95 are the putative initiation codon of the open reading frame (nucleotides

93-1244), (identified by comparison of other plant delta-12 desaturases in this application). Nucleotides 1242-1244 are the termination codon. Nucleotides 1 to 92 and 1245-1372 are the 5' and 3' untranslated nucleotides, respectively. The 383 amino acid protein sequence in SEQ ID NO:2 is that deduced from the open reading frame and has an estimated molecular weight of 44 kD.

The gene corresponding to SEQ ID NO:1 was isolated by screening an Arabidopsis genomic DNA library using radiolabeled pSF2b cDNA insert, purifying the positively-hybridizing plaque, and subcloning a 6 kB Hind III insert fragment from the phage DNA in pBluescript vector. The sequence of 2973 nucleotides of the gene is shown in SEQ ID NO:15. Comparison of the sequences of the gene (SEQ ID NO:15) and the cDNA (SEQ ID NO:1) revealed the presence of a single intron of 1134 bp at a position between nucleotide positions 88 and 89 of the cDNA, which is 4 nucleotides 5' to the initiation codon.

The 1.6 kB Eco RI-Bam HI genomic border fragment insert in pS1658 was also partially sequenced from the Bam HI and Eco RI ends. Comparison of the nucleotide sequences of the gene (SEQ ID NO:15), the cDNA (SEQ ID NO:1), the border fragment, and the published sequence of the left end of T-DNA (Yadav et al., (1982) Proc. Natl. Acad. Sci. 79:6322-6326) revealed that a) the sequence of the first 451 nucleotides of the border fragment from the Bam HI end is collinear with that of nucleotides 539 (Bam HI site) to 89 of the cDNA, b) from the Eco RI end, the border fragment is collinear from nucleotides 1 to 61 with that of the left end of T-DNA (except for a deletion of 9 contiguous nucleotides at position 42 in the border fragment), and is collinear from nucleotides 57 to 104 with that of nucleotides

41-88 of the cDNA, and c) the sequence divergences between the border fragment and the cDNA are due to the presence of the intron in the border fragment. These results show that the T-DNA disrupted the microsomal delta-12 desaturase gene in the transcribed region between the promoter and the coding region and 5' to the intron in the untranslated sequence.

A phage DNA containing Arabidopsis microsomal delta-12 desaturase gene was used as a RFLP marker on a Southern blot containing genomic DNA from several progeny of Arabidopsis thaliana (ecotype Wassileskija and marker line W100 ecotype Landesberg background) digested with Hind III. This mapped the microsomal delta-12 desaturase gene 13.6 cM proximal to locus c3838, 9.2 cM distal to locus 1At228, and 4.9 cM proximal to Fad D locus on chromosome 3 [Koorneef, M. et al., (1993) in Genetic Maps, Ed. O'Brien, S. J.; Yadav et al. (1993) Plant Physiology 103:467-476]. This position corresponds closely to previously suggested locus for microsomal delta-12 desaturation (*Fad 2*) [Hugly, S. et al., (1991) Heredity 82:4321].

The open reading frames in SEQ ID NO:1 and in sequences encoding Arabidopsis microsomal delta-15 desaturase [WO 9311245], Arabidopsis plastid delta-15 desaturase [WO 9311245], and cyanobacterial desaturase, *des A*, [Wada, et al., Nature (1990) 347:200-203; Genbank ID:CSDESA; GenBank Accession No:X53508] as well as their deduced amino acid sequences were compared by the method of Needleman et al. [J. Mol. Biol. (1970) 48:443-453] using gap weight and gap length weight values of 5.0 and 0.3, respectively, for the nucleotide sequences and 3.0 and 0.1, respectively, for protein sequences. The overall identities are summarized in Table 2.

TABLE 2

Percent Identity Between Different Fatty Acid Desaturases at the Nucleotide and Amino Acid Levels

		a3	ad	des A
a2	nucleotide	48(8 gaps)	46(6 gaps)	43(10 gaps)
	amino acid	39(9 gaps)	34(8 gaps)	24(10 gaps)
a3	nucleotide	-	65(1 gap)	43(9 gaps)
	amino acid	-	65(2 gaps)	26(11 gaps)
ad	nucleotide	-	-	43(9 gaps)
	amino acid	-	-	26(11 gaps)

a2, a3, ad, and *des A* refer, respectively, to SEQ ID NO:1/2, Arabidopsis microsomal delta-15 desaturase, Arabidopsis plastid delta-15 desaturase, and cyanobacterial desaturase, *des A*. The percent identities in each comparison are shown at both the nucleotide and amino acid levels; the number of gaps imposed by the comparisons are shown in brackets following the percent identities. As expected on the basis of unsuccessful attempts in using delta-15 fatty acid nucleotide sequences as hybridization probes to isolate nucleotide sequences encoding microsomal delta-12 fatty acid desaturase, the overall homology at the nucleotide level between microsomal delta-12 fatty acid desaturase (SEQ ID NO:1) and the nucleotide sequences encoding the other three desaturases is poor (ranging between 43% and 48%). At the amino acid level too, the microsomal delta-12 fatty acid desaturase (SEQ ID NO:2) is poorly related to cyanobacterial *des A* (less than 24% identity) and the plant delta-15 desaturases (less than 39% identity).

While the overall relatedness between the deduced amino acid sequence of the said invention and the published fatty acid desaturases is limited, more significant identities are observed in shorter stretches

of amino acid sequences in the above comparisons. These results confirm d that the T-DNA in line 658-75 had interrupted the normal expression of a fatty acid desaturase gene. Based on the fatty acid phenotype of homozygous mutant line 658-75, Applicants concluded that SEQ ID NO:1 encoded the delta-12 desaturase. Further, Applicants concluded that it was the microsomal delta-12 desaturase, and not the chloroplastic delta-12 desaturase, since: a) the mutant phenotype was expressed strongly in the seed but expressed poorly, if at all, in the leaf of line 658-75, and b) the delta-12 desaturase polypeptide, by comparison to the microsomal and plastid delta-15 desaturase polypeptides [WO 9311245], did not have an N-terminal extension of a transit peptide expected for a nuclear-encoded plastid desaturase.

Plasmid p92103 was deposited on October 16, 1992 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 69095.

<u>Expression Of Microsomal Delta-12 Fatty Acid Desaturase In Arabidopsis *Fad2-1* Mutant To Complement Its Mutation In Delta-12 Fatty Acid Desaturation</u>

To confirm the identity of SEQ ID NO:1 (<u>Arabidopsis</u> microsomal delta-12 fatty acid desaturase cDNA) a chimeric gene comprising of SEQ ID NO:1 was transformed into an <u>Arabidopsis</u> mutant affected in microsomal delta-12 fatty acid desaturation. For this, the ca. 1.4 kb Eco RI fragment containing the cDNA (SEQ ID NO:1) was isolated from plasmid p92103 and sub-cloned in pGA748 vector [An et. al.(1988) Binary Vectors. In: Plant Molecular Biology Manual. Eds Gelvin, S. B. et al. Kluwer Academic Press], which was previously linearized with Eco RI restriction enzyme. In one of the resultant binary plasmid, designated pGA-Fad2, the cDNA was placed

in the sense orientation behind the CaMV 35S promotor of the vector to provide constitutive expression.

Binary vector pGA-Fad2 was transformed by the freeze/thaw method [Holsters et al. (1978) Mol. Gen. Genet. 163:181-187] into Agrobacterium tumefaciens strain R1000, carrying the Ri plasmid pRiA4b from Agrobacterium rhizogenes [Moore et al., (1979) Plasmid 2:617-626] to result in transformants R1000/pGA-Fad2.

Agrobacterium strains R1000 and R1000/pGA-Fad2 were used to transform Arabidopsis mutant fad2-1 [Miquel, M. & Browse, J. (1992) Journal of Biological Chemistry 267:1502-1509] and strain R1000 was used to transform wild type Arabidopsis. Young bolts of plants were sterilized and cut so that a single node was present in each explant. Explants were inoculated by Agrobacteria and incubated at 25°C in the dark on drug-free MS minimal organics medium with 30 g/L sucrose (Gibco). After four days, the explants were transferred to fresh MS medium containing 500 mg/L cefotaxime and 250 mg/ml carbenicillin for the counterselection of Agrobacterium. After 5 days, hairy roots derived from R1000/pGA-Fad2 transformation were excised and transferred to the same medium containing 50 mg/ml kanamycin. Fatty acid methyl esters were prepared from 5-10 mm of the roots essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H_2SO_4 in methanol was used as the methylation reagent and samples were heated for 1.5 h at 80°C to effect the methanolysis of the seed triglycerides. The results are shown in Table 3. Root samples 41 to 46, 48 to 51, 58, and 59 are derived from transformation of fad2-1 plants with R1000/pGA Fad2; root samples 52, 53, and 57 were derived from transformation of fad2-1 plants with R1000 and serve as controls; root sample 60 is derived from

transformation of wild type Arabidopsis with R1000 and also serves as a control.

TABLE 3

Fatty acid Composition in Transgenic Arabidopsis fad2-1 Hairy Roots Transformed with Agrobacterium R1000/pGA-fad2

Sample	16:0	16:1	18:0	18:1	18:2	18:3
41	24.4	1.8	1.7	5.0	29.4	33.8
42	25.6	3.7	1.3	20.0	22.0	27.5
43	23.6	-	1.6	7.2	27.6	36.1
44	24.4	1.3	4.6	16.0	18.1	33.6
45	20.7	-	8.1	44.7	11.8	14.8
46	20.1	-	1.8	7.5	33.7	36.0
48	26.1	2.9	2.1	9.5	17.6	33.4
49	30.8	1.0	2.4	8.7	18.7	31.1
50	19.8	1.9	3.3	27.7	21.8	24.4
51	20.9	1.1	5.0	13.7	25.0	32.1
58	23.5	0.3	1.4	3.6	22.1	45.9
59	22.6	0.6	1.4	2.8	29.9	40.4
52, cont.	12.3	-	2.6	64.2	4.6	16.4
53, cont.	20.3	9.1	2.2	55.2	1.7	9.2
57, cont.	10.4	2.4	0.7	65.9	3.8	12.7
60,WT	23.0	1.7	0.8	6.0	35.0	31.8

These results show that expression of Arabidopsis microsomal delta-12 desaturase in a mutant Arabidopsis lacking delta-12 desaturation can result in partial to complete complementation of the mutant. The decrease in oleic acid levels in transgenic roots is accompanied by increases in the levels of both 18:2 and 18:3. Thus, overexpression of this gene in other oil crops, especially canola, which is a close relative of Arabidopsis and which naturally has high levels of 18:1 in seeds, is also expected to result in higher levels of 18:2, which in conjunction with

the overexpression of the microsomal delta-15 fatty acid desaturase will result in very high levels of 18:3.

Using Arabidopsis Microsomal Delta-12 Desaturase cDNA as a Hybridization Probe to Isolate Microsomal Delta-12 Desaturase cDNAs from Other Plant Species

Evidence for conservation of the delta-12 desaturase sequences amongst species was provided by using the Arabidopsis cDNA insert from pSF2b as a hybridization probe to clone related sequences from Brassica napus, and soybean. Furthermore, corn and castor bean microsomal delta-12 fatty acid desaturase were isolated by PCR using primers made to conserved regions of microsomal delta-12 desaturases.

Cloning of a Brassica napus Seed cDNA Encoding Seed Microsomal Delta-12 Fatty Acid Desaturase

For the purpose of cloning the Brassica napus seed cDNA encoding a delta-12 fatty acid desaturase, the cDNA insert from pSF2b was isolated by digestion of pSF2b with EcoR I followed by purification of the 1.2 kb insert by gel electrophoresis. The 1.2 kb fragment was radiolabeled and used as a hybridization probe to screen a lambda phage cDNA library made with poly A^+ mRNA from developing Brassica napus seeds 20-21 days after pollination. Approximately 600,000 plaques were screened under low stringency hybridization conditions (50 mM Tris pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 ug denatured calf thymus DNA and 50°C) and washes (two washes with 2X SSC, 0.5% SDS at room temperature for 15 min each, then twice with 0.2X SSC, 0.5% SDS at room temperature for 15 min each, and then twice with 0.2X SSC, 0.5% SDS at 50°C for 15 min each). Ten strongly-hybridizing phage were plaque-purified and the size of the cDNA inserts was determined by PCR amplication of the insert using phage as template and

T3/T7 oligomers for primers. Two of these phages, 165D and 165F, had PCR amplified inserts of 1.6 kb and 1.2 kb respectively and these phages were also used to excise the phagemids as described above. The phagemid derived from phage 165D, designated pCF2-165D, contained a 1.5 kb insert which was sequenced completely on one strand. SEQ ID NO:3 shows the 5' to 3' nucleotide sequence of 1394 base pairs of the Brassica napus cDNA which encodes delta-12 desaturase in plasmid pCF2-165d. Nucleotides 99 to 101 and nucleotides 1248 to 1250 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 99 to 1250). Nucleotides 1 to 98 and 1251 to 1394 are, respectively, the 5' and 3' untranslated nucleotides. The 383 amino acid protein sequence deduced from the open reading frame in SEQ ID NO:3 is shown in SEQ ID NO:4. While the other strand can easily be sequenced for confirmation, comparisons of SEQ ID NOS:1 and 3 and of SEQ ID NOS:2 and 4, even admitting of possible sequencing errors, showed an overall homology of approximately 84% at both the nucleotide and amino acid levels, which confirmed that pCF2-165D is a Brassica napus seed cDNA that encoded delta-12 desaturase. Plasmid pCF2-165D has been deposited on October 16, 1992 with the American Type Culture Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 69094.

Cloning of a Soybean (Glycine max) cDNA Encoding Seed Microsomal Delta-12 Fatty Acid Desaturase

A cDNA library was made to poly A^+ mRNA isolated from developing soybean seeds, and screened as described above. Radiolabelled probe prepared from pSF2b as described above was added, and allowed to hybridize for 18 h at 50°C. The probes were washed as described

above. Autoradiography of the filters indicated that there were 14 strongly hybridizing plaques, and numerous weakly hybridizing plaques. Six of the 14 strongly hybridizing plaques were plaque purified as described above and the cDNA insert size was determined by PCR amplication of the insert using phage as template and T3/T7 oligomers for primers. One of these phages, 169K, had an insert sizes of 1.5 kb and this phage was also used to excise the phagemid as described above. The phagemid derived from phage 169K, designated pSF2-169K, contained a 1.5 kb insert which was sequenced completely on both strands. SEQ ID NO:5 shows the 5' to 3' nucleotide sequence of 1473 base pairs of soybean (Glycine max) cDNA which encodes delta-12 desaturase in plasmid pSF2-169K. Nucleotides 108 to 110 and nucleotides 1245 to 1247 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 108 to 1247). Nucleotides 1 to 107 and 1248 to 1462 are, respectively, the 5' and 3' untranslated nucleotides. The 380 amino acid protein sequence deduced from the open reading frame in SEQ ID NO:5 is shown in SEQ ID NO:6. Comparisons of SEQ ID NOS:1 and 5 and of SEQ ID NOS:2 and 6, even admitting of possible sequencing errors, showed an overall homology of approximately 65% at the nucleotide level and approximately 70% at the amino acid level, which confirmed that pSF2-169K is a soybean seed cDNA that encoded delta-12 desaturase. A further description of this clone can be obtained by comparison of the SEQ ID NO:1, SEQ ID NO:3, and SEQ ID NO:5 and by analyzing the phenotype of transgenic plants produced by using chimeric genes incorporating the insert of pSF2-169K, in sense or antisense orientation, with suitable regulatory sequences. Plasmid pSF2-169K was deposited on October 16, 1992 with the American Type Culture

Collection of Rockville, Maryland under the provisions of the Budapest Treaty and bears accession number ATCC 69092.

Cloning of a Corn (Zea mays) cDNA Encoding Seed Microsomal Delta-12 Fatty Acid Desaturase

Corn microsomal delta-12 desaturase cDNA was isolated using a PCR approach. For this, a cDNA library was made to poly A^+ RNA from developing corn embryos in Lambda Zap II vector. This library was used as template for PCR using sets of degenerate oligomers NS3 (SEQ ID NO:13) and RB5A/B (SEQ ID NOS:16 and 17) as sense and antisense primers, respectively. NS3 and RB5A/B correspond to stretches of amino acids 101-109 and 318-326, respectively, of SEQ ID NO:2, which are conserved in most microsomal delta-12 desaturases (for example, SEQ ID NOS:2, 4, 6, 8). PCR was carried out using a PCR kit (Perkin-Elmer) by 40 cycles of 94°C 1', 45°C, 1 min, and 55°C, 2 min. Analyses of the PCR products on an agarose gel showed the presence of a product of the expected size (720 bp), which was absent in control reactions containing either the sense or antisense primers alone. The fragment was gel purified and then used as a probe for screening the corn cDNA library at 60°C as described above. One positively-hybridizing plaque was purified and partial sequence determination of its cDNA showed it to be a nucleotide sequence encoding microsomal delta-12 desaturase but truncated at the 3' end. The cDNA insert encoding the partial desaturase was gel isolated and used to probe the corn cDNA library again. Several positive plaques were recovered and characterized. DNA sequence analysis revealed that all of these clones seem to represent the same sequence with the different length of 5' or 3' ends. The clone containing the longest insert,

designated pFad2#1, was sequenced completely. The total length of the cDNA is 1790 bp (SEQ ID NO:7) comprising of an open reading frame from nucleotide 165 to 1328 bp that encoded a polypeptide of 388 amino acids. The deduced amino acid sequence of the polypeptide (SEQ ID NO:8) shared overall identities of 71%, 40%, and 38% to Arabidopsis microsomal delta-12 desaturase, Arabidopsis microsomal delta-15 desaturase, and Arabidopsis plastid delta-15 desaturase, respectively. Furthermore, it lacked an N-terminal amino acid extension that would indicate it is a plastid enzyme. Based on these considerations, it is concluded that it encodes a microsomal delta-12 desaturase.

Isolation of cDNAs Encoding Delta-12 Microsomal Fatty Acid Desaturases and Desaturase-Related Enzymes from Castor Bean Seed

Polysomal mRNA was isolated from castor beans of stages I-II (5-10 DAP) and also from castor beans of stages IV-V (20-25 DAP). Ten ng of each mRNA was used for separate RT-PCR reactions, using the Perkin-Elmer RT-PCR kit. The reverse transcriptase reaction was primed with random hexamers and the PCR reaction with degenerate delta-12 desaturase primers NS3 and NS9 (SEQ ID NOS:13 and 14). The annealing-extension temperature of the PCR reaction was 50°C. A DNA fragment of approx. 700 bp was amplified from both stage I-II and stage IV-V mRNA. The amplified DNA fragment from one of the reactions was gel purified and cloned into a pGEM-T vector using the Promega pGEM-T PCR cloning kit to create the plasmid pRF2-1C. The 700 bp insert in pRF2-1C was sequenced, as described above, and the resulting DNA sequence is shown in SEQ ID NO:9. The DNA sequence in SEQ ID NO:9 contains an open-reading frame encoding 219 amino acids (SEQ ID NO:10) which has 81% identity (90% similarity) with amino acids 135 to 353 of

the *Arabidopsis* microsomal delta-12 desaturase described in SEQ ID NO:2. The cDNA insert in pRF2-1C is therefore a 676 bp fragment of a full-length cDNA encoding a castor bean seed microsomal delta-12 desaturase. The full length castor bean seed microsomal delta-12 desaturase cDNA may isolated by screening a castor seed cDNA library, at 60°C, with the labeled insert of pRF2-1C as described in the example above. The insert in pRF2-1C may also be used to screen castor bean libraries at lower temperatures to isolate delta-12 desaturase-related sequences, such as the delta-12 hydroxylase.

A cDNA library made to poly A^+ mRNA isolated from developing castor beans (stages IV-V, 20-25 DAP) was screened as described above. Radiolabeled probe prepared from pSF2b or pRF2-1C, as described above, were added, and allowed to hybridize for 18 h at 50°C. The filters were washed as described above. Autoradiography of the filters indicated that there were numerous hybridizing plaques, which appeared either strongly-hybridising or weakly-hybridising. Three of the strongly hybridisng plaques (190A-41, 190A-42 and 190A-44) and three of the weakly hybridising plaques, (190B-41, 190b-43 and 197c-42), were plaque purified using the methods described above. The cDNA insert size of the purified phages were determined by PCR amplication of the insert using phage as template and lambda-gt11 oligomers (Clontech lambda-gt11 Amplimers) for primers. The PCR-amplified inserts of the amplified phages were subcloned into pBluescript (Pharmacia) which had been cut with Eco RI and filled in with Klenow (Sambrook et al. (Molecular Cloning, A Laboratory Approach, 2nd. ed. (1989) Cold Spring Harbor Laboratory Press). The resulting plasmids were called pRF190a-41, pRF190a-42, pRF190a-44, pRF190b-41, pRF190b-43 and

pRF197c-42. All of the inserts were about 1.1 kb with the exception of pRF197c-42 which was approx. 1.5 kb. The inserts in the plasmids were sequenced as described above. The insert in pRF190b-43 did not contain any open reading frame and was not identified. The inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 were identical. The insert in pRF197c-42 contained all of the nucleotides of the inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 plus an additional approx. 400 bp. It was deduced therefore that the insert in pRF197c-42 was a longer version of the inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 and all were derived from the same full-length mRNA. The complete cDNA sequence of the insert in plasmid pRF197c-42 is shown in SEQ ID NO:11. The deduced amino acid sequence of SEQ ID NO:11, shown in SEQ ID NO:12, is 78.5% identical (90% similarity) to the castor microsomal delta-12 desaturase described above (SEQ ID NO:10) and 66% identical (80% similarity) to the Arabidopsis delta-12 desaturase amino acid sequence in SEQ ID NO:2. These similarities confirm that pRF197c-42 is a castor bean seed cDNA that encodes a microsomal delta-12 desaturase or a microsomal delta-12 desaturase-related enzyme, such as a delta-12 hydroxylase. Specific PCR primers for pRF2-1C and pRF197c-42 were made. For pRF2-1c the upstream primer was bases 180 to 197 of the cDNA sequence in SEQ ID NO:9. For pRF197c-42 the upstream primer was bases 717 to 743 of the cDNA sequence in SEQ ID NO:11. A common downstream primer was made corresponding to the exact complement of the nucleotides 463 to 478 of the sequence described in SEQ ID NO:9. Using RT-PCR with random hexamers and the above primers it was observed that the cDNA contained in pRF2-1C is expressed in both Stage I-II and Stage IV-V castor bean seeds whereas the cDNA contained in plasmid

pRF197c-42 is expressed only in Stage IV-V castor b an seeds, i.e., it is only expressed in tissue actively synthesizing ricinoleic acid. Thus, it is possible that this cDNA encodes a delta-12 hydroxylase.

There is enough deduced amino acid sequence from the two castor sequences described in SEQ ID NOS:10 and 12 to compare the highly conserved region corresponding to amino acids 311 to 353 of SEQ ID NO:2. When SEQ ID NOS:2, 4, 6, 8, and 10 are aligned by the Hein method described above the consensus sequence corresponds exactly to the amino acids 311 to 353 of SEQ ID NO:2. All of the seed microsomal delta-12 desaturases described above have a high degree of identity with the consensus over this region, namely Arabidopsis (100% identity), soybean (90% identity), corn (95% identity), canola (93% identity) and one (pRF2-1c) of the castor bean sequences (100% identity). The other castor bean seed delta-12 desaturase or desaturase-related sequence (pRF197c-42) however has less identity with the consensus, namely 81% for the deduced amino acid sequence of the insert in pRF197c-42 (described in SEQ ID NO:12). Thus while it remains possible that the insert in pRF197c-42 encodes a microsomal delta-12 desaturase, this observation supports the hypothesis that it encodes a desaturase-related sequence, namely the delta-12 hydroxylase.

An additional approach to cloning a castor bean seed delta-12 hydroxylase is the screening of a differential population of cDNAs. A lambda-Zap (Stratagene) cDNA library made to polysomal mRNA isolated from developing castor bean endosperm (stages IV-V, 20-25 DAP) was screened with ^{32}P-labeled cDNA made from polysomal mRNA isolated from developing castor bean endosperm (stage I-II, 5-10 DAP) and with ^{32}P-labeled cDNA made from polysomal mRNA isolated from developing

castor bean endosperm (stages IV-V, 20-25 DAP). The library was scre ned at a density of 2000 plaques per 137 mm plate so that individual plaques were isolated. About 60,000 plaques were screened and plaques which hybridised with late (stage IV/V) cDNA but not early (stage I/II) cDNA, which corresponded to about 1 in every 200 plaques, were pooled.

The library of differentially expressed cDNAs may be screened with the castor delta-12 desaturase cDNA described above and/or with degenerate oligonucleotides based on sequences of amino conserved among delta-12 desaturases to isolate related castor cDNAs, including the cDNA encoding the delta-12 oleate hydroxylase enzyme. These regions of amino acid conservation may include, but are not limited to amino acids 101 to 109, 137 to 145, and 318 to 327 of the amino acid sequence described in SEQ ID NO:2 or any of the sequences described in Table 7 below. Examples of such oligomers are SEQ ID NOS:13, 14, 16, and 17. The insert in plasmid pCF2-197c may be cut with Eco RI to remove vector sequences, purified by gel electrophoresis and labeled as described above. Degenerate oligomers based on the above conserved amino acid sequences may be labeled with ^{32}P as described above. The cDNAs cloned from the developing endosperm difference library which do not hybridize with early mRNA probe but do hybridize with late mRNA probe and hybridize with either castor delta-12 desaturase cDNA or with an oligomer based on delta-12 desaturase sequences are likely to be the castor delta-12 hydroxylase. The pBluescript vector containing the putative hydroxylase cDNA can be excised and the inserts directly sequenced, as described above.

Clones such as pRF2-1C and pRF197c-42, and other clones from the differential screening, which, based on their DNA sequence, are less related to castor bean seed

microsomal delta-12 desaturases and are not any of the known fatty-acid desaturases described above or in WO 9311245, may be expressed, for example, in soybean embryos or another suitable plant tissue, or in a microorganism, such as yeast, which does not normally contain ricinoleic acid, using suitable expression vectors and transformation protocols. The presence of novel ricinoleic acid in the transformed tissue(s) expressing the castor cDNA would confirm the identity of the castor cDNA as DNA encoding for an oleate hydroxylase.

Sequence Comparisons Among Seed Microsomal Delta-12 Desaturases

The percent overall identities between coding regions of the full-length nucleotide sequences encoding microsomal delta-12 desaturases was determined by their alignment by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453) using gap weight and gap length weight values of 5.0 and 0.3 (Table 4). Here, a2, c2, s2, z2 and *des A* refer, respectively, to the nucleotide sequences encoding microsomal delta-12 fatty acid desaturases from Arabidopsis (SEQ ID NO:1), Brassica napus (SEQ ID NO:3), soybean (SEQ ID NO:5), corn (SEQ ID NO:7), and cyanobacterial *des A*, whereas r2 refers to the microsomal delta-12 desaturase or desaturase-related enzyme from castor bean (SEQ ID NO:12).

TABLE 4

Percent Identity Between the Coding Regions of Nucleotide Sequences Encoding Different Microsomal Delta-12 Fatty Acid Desaturases

	c2	s2	z2	*des A*
a2	84	66	64	43
c2	-	65	62	42
s2	-	-	62	42

The overall relatedness between the deduced amino acid sequences of microsomal delta-12 desaturases or desaturase-related enzymes of the invention (i.e., SEQ ID NOS:2, 4, 6, 8, and 12) determined by their alignment by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453) using gap weight and gap length weight values of 3.0 and 0.1, respectively, is shown in Table 5. Here a2, c2, s2, z2 and *des A* refer, respectively, to microsomal delta-12 fatty acid desaturases from Arabidopsis (SEQ ID NO:2), Brassica napus (SEQ ID NO:4), soybean (SEQ ID NO:6), corn (SEQ ID NO:8), and cyanobacterial *des A*, whereas r2 refers to the microsomal desaturase or desaturase-related enzyme from castor bean (SEQ ID NO:12). The relatedness between the enzymes is shown as percent overall identity/percent overall similarity.

TABLE 5

Relatedness Between Different Microsomal Delta-12 Fatty Acid Desaturases

	c2	s2	r2	z2	*des A*
a2	84/89	70/85	66/80	71/83	24/50
c2	-	67/80	63/76	69/79	24/51
s2	-	-	67/83	66/82	23/49
r2	-	-	-	61/78	24/51
z2	-	-	-	-	25/49

The high degree of overall identity (60% or greater) at the the amino acid levels between the Brassica napus, soybean, castor and corn enzymes with that of Arabidopsis microsomal delta-12 desaturase and their lack of an N-terminal extension of a transit peptide expected for a nuclear-encoded chloroplast desaturase leads Applicants to conclude that SEQ ID NOS:4, 6, 8, 10, and 12 encode the microsomal delta-12

desaturases or desaturase-related enzymes. Further confirmation of this identity will come from biological function, that is, by analyzing the phenotype of transgenic plants or other organisms produced by using chimeric genes incorporating the above-mentioned sequences in sense or antisense orientation, with suitable regulatory sequences. Thus, one can isolate cDNAs and genes for homologous fatty acid desaturases from the same or different higher plant species, especially from the oil-producing species. Furthermore, based on these comparisons, the Applicants expect all higher plant microsomal delta-12 desaturases from all higher plants to show an overall identity of 60% or more and to be able to readily isolate homologous fatty acid desaturase sequences using SEQ ID NOS:1, 3, 5, 7, 9, and 11 by sequence-dependent protocols.

The overall percent identity at the amino acid level, using the above alignment method, between selected plant desaturases is illustrated in Table 6.

TABLE 6

Percent Identity Between Selected Plant Fatty Acid Desaturases at the Amino Acid Level

	a3	aD	c3	cD	S3
a2	38	33	38	35	34
a3	-	65	93	66	67
aD	-	-	66	87	65
c3	-	-	-	67	67
cD	-	-	-	-	65

In Table 6, a2, a3, ad, c3, cD, and S3 refer, respectively, to SEQ ID NO:2, *Arabidopsis* microsomal delta-15 desaturase, *Arabidopsis* plastid delta-15 desaturase, canola microsomal delta-15 desaturase, canola plastid delta-15 desaturase, and soybean microsomal delta-15 desaturase. Based on these

comparisons, the delta-15 d saturases, of both microsomal and plastid types, have overall identities of 65% or more at the amino acid level, even when from the same plant species. Based on the above the Applicants expect microsomal delta-12 desaturases from all higher plants to show similar levels of identity (that is, 60% or more identity at the amino acid level) and that SEQ ID NOS:1, 3, 5, 7, and 9 can also be used as hybridization probe to isolate homologous delta-12 desaturase sequences, and possibly for sequences for fatty acid desaturase-related enzymes, such as oleate hydroxylase, that have an overall amino acid homology of 50% or more.

Similar alignments of protein sequences of plant microsomal fatty acid delta-12 desaturases [SEQ ID NOS:2, 4, 6, and 8] and plant delta-15 desaturases [microsomal and plastid delta-15 desaturases from *Arabidopsis* and *Brassica napus*, WO 9311245] allows identification of amino acid sequences conserved between the different desaturases (Table 7).

TABLE 7

Amino Acid Sequences Conserved Between Plant Microsomal Delta-12 Desaturases and Microsomal and Plastid Delta-15 Desaturases

Region	Conserved AA Positions in SEQ ID NO:2	Consensus Conserved AA Sequence in Δ^{12}Desaturases	Consensus Conserved AA Sequence in Δ^{15}Desaturases	Consensus AA Sequence

Table 7 shows twelve regions of conserved amino acid sequences, designated A-L (column 1), whose positions in SEQ ID NO:2 are shown in column 2. The consensus sequences for these regions in plant delta-12 fatty acid desaturases and plant delta-15 fatty acid desaturases are shown in columns 3 and 4, respectively; amino acids are shown by standard abbreviations, the underlined amino acids are conserved between the delta-12 and the delta-15 desaturases, and amino acids in brackets represent substitutions found at that position. The consensus sequence of these regions are shown in column 5. These short conserved amino acids and their relative positions further confirm that the isolated isolated cDNAs encode a fatty acid desaturase.

Isolation of Nucleotide Sequences Encoding Homologous and Heterologous Fatty acid Desaturases and Desaturase-like Enzymes

Fragments of the instant invention may be used to isolate cDNAs and genes of homologous and heterologous fatty acid desaturases from the same species as the fragments of the invention or from different species. Isolation of homologous genes using sequence-dependent protocols is well-known in the art and Applicants have demonstrated that *Arabidopsis* microsomal delta-12 desaturase cDNA sequence can be used to isolate cDNA for related fatty acid desaturases from *Brassica napus*, soybean, corn and castor bean.

More importantly, one can use the fragments containing SEQ ID NOS:1, 3, 5, 7, and 9 or their

smaller, more conserved regions to isolate novel fatty acid desaturases and fatty acid desaturase-related enzymes.

In a particular embodiment of the present invention, regions of the nucleic acid fragments of the invention that are conserved between different desaturases may be used by one skilled in the art to design a mixture of degenerate oligomers for use in sequence-dependent protocols aimed at isolating nucleic acid fragments encoding homologous or heterologous fatty acid desaturase cDNA's or genes. For example, in the polymerase chain reaction (Innis, et al., Eds, (1990) PCR Protocols: A Guide to Methods and Applications, Academic Press, San Diego), two short pieces of the present fragment of the invention can be used to amplify a longer fatty acid desaturase DNA fragment from DNA or RNA. The polymerase chain reaction may also be performed on a library of cloned nucleotide sequences with one primer based on the fragment of the invention and the other on either the poly A^+ tail or a vector sequence. These oligomers may be unique sequences or degenerate sequences derived from the nucleic acid fragments of the invention. The longer piece of homologous fatty acid desaturase DNA generated by this method could then be used as a probe for isolating related fatty acid desaturase genes or cDNAs from Arabidopsis or other species and subsequently identified by differential screening with known desaturase sequences and by nucleotide sequence determination. The design of oligomers, including long oligomers using deoxyinosine, and "guessmers" for hybridization or for the polymerase chain reaction are known to one skilled in the art and discussed in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). Short stretches of

amino acid sequences that are conserved between cyanobacterial delta-12 desaturase (Wada et al., Nature (1990) 347:200-203) and plant delta-15 desaturases [WO 9311245] were previously used to make oligonucleotides that were degenerate and/or used deoxyinosine/s. One set of these oligomers made to a stretch of 12 amino acids conserved between cyanobacterial delta-12 desaturase and higher plant delta-15 desaturases was successful in cloning the plastid delta-12 desaturase cDNAs; these plant desaturases have more than 50% identity to the cyanobacterial delta-12 desaturase. Some of these oligonucleotides were also used as primers to make polymerase chain reaction (PCR) products using poly A^+ RNA from plants. However, none of the oligonucleotides and the PCR products were successful as radiolabeled hybridization probes in isolating nucleotide sequences encoding microsomal delta-12 fatty acid desaturases. Thus, as expected, none of the stretches of four or more amino acids conserved between *Arabidopsis* delta-12 and *Arabidopsis* delta-15 desaturases are identical in the cyanobacterial desaturase, just like none of the stretches of four or more amino acids conserved between *Arabidopsis* delta-15 and the cyanobacterial desaturase are identical in SEQ ID NO:2. Stretches of conserved amino acids between the present invention and delta-15 desaturases now allow for the design of oligomers to be used to isolate sequences encoding other desaturases and desaturase-related enzymes. For example, conserved stretches of amino acids between delta-12 desaturase and delta-15 desaturase, shown in Table 7, are useful in designing long oligomers for hybridization as well as shorter ones for use as primers in the polymerase chain reaction. In this regard, sequences conserved between delta-12 and delta-15 desaturases (shown in Table 7)

would be particularly useful. The consensus sequences will also take into account conservative substitutions known to one skilled in the art, such as Lys/Arg, Glu/Asp, Ile/Val/Leu/Met, Ala/Gly, Gln/Asn, and Ser/Thr. Amino acid sequences as short as four amino acids long can successfully be used in PCR [Nunberg et. al. (1989) Journal of Virology 63:3240-3249]. Amino acid sequences conserved between delta-12 desaturases (SEQ ID NOS:2, 4, 6, 8, and 10) may also be used in sequence-dependent protocols to isolate fatty acid desaturases and fatty acid desaturase-related enzymes expected to be more related to delta-12 desaturases, such as the oleate hydroxylase from castor bean. Particularly useful are conserved sequences in column 3 (Table 7), since they are also conserved well with delta-15 desaturases (column 4, Table 7).

Determining the conserved amino acid sequences from diverse desaturases will also allow one to identify more and better consensus sequences that will further aid in the isolation of novel fatty acid desaturases, including those from non-plant sources such as fungi, algae (including the desaturases involved in the desaturations of the long chain n-3 fatty acids), and even cyano-bacteria, as well as other membrane-associated desaturases from other organisms.

The function of the diverse nucleotide fragments encoding fatty acid desaturases or desaturase-related enzymes that can be isolated using the present invention can be identified by transforming plants with the isolated sequences, linked in sense or antisense orientation to suitable regulatory sequences required for plant expression, and observing the fatty acid phenotype of the resulting transgenic plants. Preferred target plants for the transformation are the same as the source of the isolated nucleotide fragments when the

goal is to obtain inhibition of the corresponding endogenous gene by antisense inhibition or cosuppression. Preferred target plants for use in expression or overexpression of the isolated nucleic acid fragments are wild type plants or plants with known mutations in desaturation reactions, such as the Arabidopsis mutants fadA, fadB, fadC, fadD, fad2, and fad3; mutant flax deficient in delta-15 desaturation; or mutant sunflower deficient in delta-12 desaturation. Alternatively, the function of the isolated nucleic acid fragments can be determined similarly via transformation of other organisms, such as yeast or cyanobacteria, with chimeric genes containing the nucleic acid fragment and suitable regulatory sequences followed by analysis of fatty acid composition and/or enzyme activity.

Overexpression of the Fatty Acid Desaturase Enzymes in Transgenic Species

The nucleic acid fragment(s) of the instant invention encoding functional fatty acid desaturase(s), with suitable regulatory sequences, can be used to overexpress the enzyme(s) in transgenic organisms. An example of such expression or overexpression is demonstrated by transformation of the Arabidopsis mutant lacking oleate desaturation. Such recombinant DNA constructs may include either the native fatty acid desaturase gene or a chimeric fatty acid desaturase gene isolated from the same or a different species as the host organism. For overexpression of fatty acid desaturase(s), it is preferable that the introduced gene be from a different species to reduce the likelihood of cosuppression. For example, overexpression of delta-12 desaturase in soybean, rapeseed, or other oil-producing species to produce altered levels of polyunsaturated fatty acids may be achieved by expressing RNA from the full-length cDNA found in p92103, pCF2-165D, and

pSF2-169K. Transgenic lines ov rexpressing the delta-12 desaturase, when crossed with lines overexpressing delta-15 desaturases, will result in ultrahigh levels of 18:3. Similarly, the isolated nucleic acid fragments encoding fatty acid desaturases from Arabidopsis, rapeseed, and soybean can also be used by one skilled in the art to obtain other substantially homologous full-length cDNAs, if not already obtained, as well as the corresponding genes as fragments of the invention. These, in turn, may be used to overexpress the corresponding desaturases in plants. One skilled in the art can also isolate the coding sequence(s) from the fragment(s) of the invention by using and/or creating sites for restriction endonucleases, as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press).

One particularly useful application of the claimed inventions is to repair the agronomic performance of plant mutants containing ultra high levels of oleate in seed oil. In Arabidopsis reduction in linoleate in phosphatidylcholine due to a mutation in microsomal delta-12 desaturase affected low temperature survival [Miquel, M. et. al. (1993) Proc. Natl Acad. Sci. USA 90:6208-6212]. Furthermore, there is evidence that the poor agronomic performance of canola plants containing ultra high (>80%)levels of oleate in seed is due to mutations in the microsomal delta-12 desaturase genes that reduce the level of linoleate in phosphotidylcholine of roots and leaves. That is, the mutations are not seed-specific. Thus, the root and/or leaf-specific expression (that is, with no expression in the seeds) of microsomal delta-12 desaturase activity in mutants of oilseeds with ultra-high levels of oleate in seed oil

will result in agronomically-improved mutant plants with ultra high levels of oleate in seed oil.

Inhibition of Plant Target Genes by Use of Antisense RNA

Antisense RNA has been used to inhibit plant target genes in a tissue-specific manner (see van der Krol et al., Biotechniques (1988) 6:958-976). Antisense inhibition has been shown using the entire cDNA sequence (Sheehy et al., Proc. Natl. Acad. Sci. USA (1988) 85:8805-8809) as well as a partial cDNA sequence (Cannon et al., Plant Molec. Biol. (1990) 15:39-47). There is also evidence that the 3' non-coding sequences (Ch'ng et al., Proc. Natl. Acad. Sci. USA (1989) 86:10006-10010) and fragments of 5' coding sequence, containing as few as 41 base-pairs of a 1.87 kb cDNA (Cannon et al., Plant Molec. Biol. (1990) 15:39-47), can play important roles in antisense inhibition.

The use of antisense inhibition of the fatty acid desaturases may require isolation of the transcribed sequence for one or more target fatty acid desaturase genes that are expressed in the target tissue of the target plant. The genes that are most highly expressed are the best targets for antisense inhibition. These genes may be identified by determining their levels of transcription by techniques, such as quantitative analysis of mRNA levels or nuclear run-off transcription, known to one skilled in the art.

The entire soybean microsomal delta-12 desaturase cDNA was cloned in the antisense orientation with respect to either soybean b-conglycinin, soybean KTi3, and bean phaseolin promoter and the chimeric gene transformed into soybean somatic embryos that were previously shown to serve as good model system for soybean zygotic embryos and are predictive of seed composition (Table 11). Transformed somatic embryos

showed inhibition of linoleate biosyntheis. Similarly, the entire Brassica napus microsomal delta-12 desaturase cDNA was cloned in the antisense orientation with respect to a rapeseed napin promoter and the chimeric gene transformed into B. napus. Seeds of transformed B. napus plants showed inhibition of linoleate biosynthesis. Thus, antisense inhibition of delta-12 desaturase in oil-producing species, including corn, Brassica napus, and soybean resulting in altered levels of polyunsaturated fatty acids may be achieved by expressing antisense RNA from the entire or partial cDNA encoding microsomal delta-12 desaturase.

Inhibition of Plant Target Genes by Cosuppression

The phenomenon of cosuppression has also been used to inhibit plant target genes in a tissue-specific manner. Cosuppression of an endogenous gene using the entire cDNA sequence (Napoli et al., The Plant Cell (1990) 2:279-289; van der Krol et al., The Plant Cell (1990) 2:291-299) as well as a partial cDNA sequence (730 bp of a 1770 bp cDNA) (Smith et al., Mol. Gen. Genetics (1990) 224:477-481) are known.

The nucleic acid fragments of the instant invention encoding fatty acid desaturases, or parts thereof, with suitable regulatory sequences, can be used to reduce the level of fatty acid desaturases, thereby altering fatty acid composition, in transgenic plants which contain an endogenous gene substantially homologous to the introduced nucleic acid fragment. The experimental procedures necessary for this are similar to those described above for the overexpression of the fatty acid desaturase nucleic acid fragments except that one may also use a partial cDNA sequence. For example, cosuppression of delta-12 desaturase in Brassica napus and soybean resulting in altered levels of

polyunsaturated fatty acids may be achieved by expressing in the sense orientation the entire or partial seed delta-12 desaturase cDNA found in pCF2-165D and pSF2-165K, respectively. Endogenous genes can also be inhibited by non-coding regions of an introduced copy of the gene [For example, Brusslan, J. A. et al. (1993) Plant Cell 5:667-677; Matzke, M. A. et al., Plant Molecular Biology 16:821-830]. We have shown that an Arabidopsis gene (SEQ ID NO:15) corresponding to the cDNA (SEQ ID NO:1) can be isolated. One skilled in the art can readily isolate genomic DNA containing or flanking the genes and use the coding or non-coding regions in such transgene inhibition methods.

Analysis of the fatty acid composition of roots and seeds of Arabidopsis mutants deficient in microsomal delta-12 desaturation shows that they have reduced levels of 18:2 as well as reduced levels of 16:0 (as much as 40% reduced level in mutant seeds as compared to wild type seeds) [Miquel and Browse (1990) in Plant Lipid Biochemistry, Structure, and Utilization, pages 456-458, Ed. Quinn, P. J. and Harwood, J. L., Portland Press. Reduction in the level of 16:0 is also observed in ultra high oleate mutants of B. napus. Thus, one can expect that ultra high level of 18:1 in transgenic plants due to antisense inhibition or co-supression using the claimed sequences will also reduce the level of 16:0.

Selection of Hosts, Promoters and Enhancers

A preferred class of heterologous hosts for the expression of the nucleic acid fragments of the invention are eukaryotic hosts, particularly the cells of higher plants. Particularly preferred among the higher plants are the oil-producing species, such as soybean (Glycine max), rapeseed (including Brassica napus, B. campestris), sunflower (Helianthus annus),

cotton (Gossypium hirsutum), corn (Zea mays), cocoa (Theobroma cacao), safflower (Carthamus tinctorius), oil palm (Elaeis guineensis), coconut palm (Cocos nucifera), flax (Linum usitatissimum), and peanut (Arachis hypogaea).

Expression in plants will use regulatory sequences functional in such plants. The expression of foreign genes in plants is well-established (De Blaere et al., Meth. Enzymol. (1987) 153:277-291). The source of the promoter chosen to drive the expression of the fragments of the invention is not critical provided it has sufficient transcriptional activity to accomplish the invention by increasing or decreasing, respectively, the level of translatable mRNA for the fatty acid desaturases in the desired host tissue. Preferred promoters include (a) strong constitutive plant promoters, such as those directing the 19S and 35S transcripts in cauliflower mosaic virus (Odell et al., Nature (1985) 313:810-812; Hull et al., Virology (1987) 86:482-493), (b) tissue- or developmentally-specific promoters, and (c) other transcriptional promoter systems engineered in plants, such as those using bacteriophage T7 RNA polymerase promoter sequences to express foreign genes. Examples of tissue-specific promoters are the light-inducible promoter of the small subunit of ribulose 1,5-bis-phosphate carboxylase (if expression is desired in photosynthetic tissues), the maize zein protein promoter (Matzke et al., EMBO J. (1984) 3:1525-1532), and the chlorophyll a/b binding protein promoter (Lampa et al., Nature (1986) 316:750-752).

Particularly preferred promoters are those that allow seed-specific expression. This may be especially useful since seeds are the primary source of vegetable oils and also since seed-specific expression will avoid

any potential deleterious effect in non-seed tissues. Examples of seed-specific promoters include, but are not limited to, the promoters of seed storage proteins, which can represent up to 90% of total seed protein in many plants. The seed storage proteins are strictly regulated, being expressed almost exclusively in seeds in a highly tissue-specific and stage-specific manner (Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221; Goldberg et al., Cell (1989) 56:149-160). Moreover, different seed storage proteins may be expressed at different stages of seed development.

Expression of seed-specific genes has been studied in great detail (See reviews by Goldberg et al., Cell (1989) 56:149-160 and Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221). There are currently numerous examples of seed-specific expression of seed storage protein genes in transgenic dicotyledonous plants. These include genes from dicotyledonous plants for bean b-phaseolin (Sengupta-Gopalan et al., Proc. Natl. Acad. Sci. USA (1985) 82:3320-3324; Hoffman et al., Plant Mol. Biol. (1988) 11:717-729), bean lectin (Voelker et al., EMBO J. (1987) 6:3571-3577), soybean lectin (Okamuro et al., Proc. Natl. Acad. Sci. USA (1986) 83:8240-8244), soybean Kunitz trypsin inhibitor (Perez-Grau et al., Plant Cell (1989) 1:095-1109), soybean b-conglycinin (Beachy et al., EMBO J. (1985) 4:3047-3053; pea vicilin (Higgins et al., Plant Mol. Biol. (1988) 11:683-695), pea convicilin (Newbigin et al., Planta (1990) 180:461-470), pea legumin (Shirsat et al., Mol. Gen. Genetics (1989) 215:326-331); rapeseed napin (Radke et al., Theor. Appl. Genet. (1988) 75:685-694) as well as genes from monocotyledonous plants such as for maize 15 kD zein (Hoffman et al., EMBO J. (1987) 6:3213-3221), maize 18 kD oleosin (Lee at al., Proc. Natl. Acad. Sci. USA (1991) 888:6181-6185),

barley b-hordein (Marris et al., Plant Mol. Biol. (1988) 10:359-366) and wheat glutenin (Colot et al., EMBO J. (1987) 6:3559-3564). Moreover, promoters of seed-specific genes operably linked to heterologous coding sequences in chimeric gene constructs also maintain their temporal and spatial expression pattern in transgenic plants. Such examples include use of Arabidopsis thaliana 2S seed storage protein gene promoter to express enkephalin peptides in Arabidopsis and B. napus seeds (Vandekerckhove et al., Bio/Technology (1989) 7:929-932), bean lectin and bean b-phaseolin promoters to express luciferase (Riggs et al., Plant Sci. (1989) 63:47-57), and wheat glutenin promoters to express chloramphenicol acetyl transferase (Colot et al., EMBO J. (1987) 6:3559-3564).

Of particular use in the expression of the nucleic acid fragment of the invention will be the heterologous promoters from several soybean seed storage protein genes such as those for the Kunitz trypsin inhibitor (Jofuku et al., Plant Cell (1989) 1:1079-1093; glycinin (Nielson et al., Plant Cell (1989) 1:313-328), and b-conglycinin (Harada et al., Plant Cell (1989) 1:415-425). Promoters of genes for a- and b-subunits of soybean b-conglycinin storage protein will be particularly useful in expressing the mRNA or the antisense RNA in the cotyledons at mid- to late-stages of seed development (Beachy et al., EMBO J. (1985) 4:3047-3053) in transgenic plants. This is because there is very little position effect on their expression in transgenic seeds, and the two promoters show different temporal regulation. The promoter for the a-subunit gene is expressed a few days before that for the b-subunit gene. This is important for transforming rapeseed where oil biosynthesis begins about a week

before seed storage protein synthesis (Murphy et al., J. Plant Physiol. (1989) 135:63-69).

Also of particular use will be promoters of genes expressed during early embryogenesis and oil biosynthesis. The native regulatory sequences, including the native promoters, of the fatty acid desaturase genes expressing the nucleic acid fragments of the invention can be used following their isolation by those skilled in the art. Heterologous promoters from other genes involved in seed oil biosynthesis, such as those for B. napus isocitrate lyase and malate synthase (Comai et al., Plant Cell (1989) 1:293-300), delta-9 desaturase from safflower (Thompson et al. Proc. Natl. Acad. Sci. USA (1991) 88:2578-2582) and castor (Shanklin et al., Proc. Natl. Acad. Sci. USA (1991) 88:2510-2514), acyl carrier protein (ACP) from Arabidopsis (Post-Beittenmiller et al., Nucl. Acids Res. (1989) 17:1777), B. napus (Safford et al., Eur. J. Biochem. (1988) 174:287-295), and B. campestris (Rose et al., Nucl. Acids Res. (1987) 15:7197), b-ketoacyl-ACP synthetase from barley (Siggaard-Andersen et al., Proc. Natl. Acad. Sci. USA (1991) 88:4114-4118), and oleosin from Zea mays (Lee et al., Proc. Natl. Acad. Sci. USA (1991) 88:6181-6185), soybean (Genbank Accession No: X60773) and B. napus (Lee et al., Plant Physiol. (1991) 96:1395-1397) will be of use. If the sequence of the corresponding genes is not disclosed or their promoter region is not identified, one skilled in the art can use the published sequence to isolate the corresponding gene and a fragment thereof containing the promoter. The partial protein sequences for the relatively-abundant enoyl-ACP reductase and acetyl-CoA carboxylase are also published (Slabas et al., Biochim. Biophys. Acta (1987) 877:271-280; Cottingham et al., Biochim. Biophys. Acta (1988) 954:201-207) and one skilled in the art can use

these sequences to isolate the corresponding seed genes with their promoters. Similarly, the fragments of the present invention encoding fatty acid desaturases can be used to obtain promoter regions of the corresponding genes for use in expressing chimeric genes.

Attaining the proper level of expression of the nucleic acid fragments of the invention may require the use of different chimeric genes utilizing different promoters. Such chimeric genes can be transferred into host plants either together in a single expression vector or sequentially using more than one vector.

It is envisioned that the introduction of enhancers or enhancer-like elements into the promoter regions of either the native or chimeric nucleic acid fragments of the invention will result in increased expression to accomplish the invention. This would include viral enhancers such as that found in the 35S promoter (Odell et al., Plant Mol. Biol. (1988) 10:263-272), enhancers from the opine genes (Fromm et al., Plant Cell (1989) 1:977-984), or enhancers from any other source that result in increased transcription when placed into a promoter operably linked to the nucleic acid fragment of the invention.

Of particular importance is the DNA sequence element isolated from the gene for the a-subunit of b-conglycinin that can confer 40-fold seed-specific enhancement to a constitutive promoter (Chen et al., Dev. Genet. (1989) 10:112-122). One skilled in the art can readily isolate this element and insert it within the promoter region of any gene in order to obtain seed-specific enhanced expression with the promoter in transgenic plants. Insertion of such an element in any seed-specific gene that is expressed at different times than the b-conglycinin gene will result in expression in

transgenic plants for a longer period during seed development.

The invention can also be accomplished by a variety of other methods to obtain the desired end. In one form, the invention is based on modifying plants to produce increased levels of fatty acid desaturases by virtue of introducing more than one copy of the foreign gene containing the nucleic acid fragments of the invention. In some cases, the desired level of polyunsaturated fatty acids may require introduction of foreign genes for more than one kind of fatty acid desaturase.

Any 3' non-coding region capable of providing a polyadenylation signal and other regulatory sequences that may be required for the proper expression of the nucleic acid fragments of the invention can be used to accomplish the invention. This would include 3' ends of the native fatty acid desaturase(s), viral genes such as from the 35S or the 19S cauliflower mosaic virus transcripts, from the opine synthesis genes, ribulose 1,5-bisphosphate carboxylase, or chlorophyll a/b binding protein. There are numerous examples in the art that teach the usefulness of different 3' non-coding regions.

Transformation Methods

Various methods of transforming cells of higher plants according to the present invention are available to those skilled in the art (see EPO Pub. 0 295 959 A2 and 0 318 341 A1). Such methods include those based on transformation vectors utilizing the Ti and Ri plasmids of Agrobacterium spp. It is particularly preferred to use the binary type of these vectors. Ti-derived vectors transform a wide variety of higher plants, including monocotyledonous and dicotyledonous plants (Sukhapinda et al., Plant Mol. Biol. (1987) 8:209-216; Potrykus, Mol. Gen. Genet. (1985) 199:183). Other

transformation methods are available to those skilled in the art, such as direct uptake of foreign DNA constructs (see EPO Pub. 0 295 959 A2), techniques of electroporation (Fromm et al., Nature (1986) (London) 319:791) or high-velocity ballistic bombardment with metal particles coated with the nucleic acid constructs (Kline et al., Nature (1987) (London) 327:70). Once transformed, the cells can be regenerated by those skilled in the art.

Of particular relevance are the recently described methods to transform foreign genes into commercially important crops, such as rapeseed (De Block et al., Plant Physiol. (1989) 91:694-701), sunflower (Everett et al., Bio/Technology (1987) 5:1201), and soybean (Christou et al., Proc. Natl. Acad. Sci USA (1989) 86:7500-7504.

Application to Molecular Breeding

The 1.6 kb insert obtained from the plasmid pSF2-169K was used as a radiolabelled probe on a Southern blot containing genomic DNA from soybean (*Glycine max* (cultivar Bonus) and *Glycine soja* (PI81762)) digested with one of several restriction enzymes. Different patterns of hybridization (polymorphisms) were identified in digests performed with restriction enzymes Hind III and Eco RI. These polymorphisms were used to map two pSF2-169 loci relative to other loci on the soybean genome essentially as described by Helentjaris et al., (Theor. Appl. Genet. (1986) 72:761-769). One mapped to linkage group 11 between 4404.00 and 1503.00 loci (4.5 cM and 7.1 cM from 4404.00 and 1503.00, respectively) and the other to linkage group 19 between 4010.00 and 5302.00 loci (1.9 cM and 2.7 cM from 4010.00 and 5302.00, respectively) [Rafalski, A and Tingey, S. (1993) in Genetic Maps, Ed. O' Brien, S. J.]. The use of

restriction fragment length polymorphism (RFLP) markers in plant breeding has been well-documented in the art (Tanksley et al., Bio/Technology (1989) 7:257-264). Thus, the nucleic acid fragments of the invention can be used as RFLP markers for traits linked to expression of fatty acid desaturases. These traits will include altered levels of unsaturated fatty acids. The nucleic acid fragment of the invention can also be used to isolate the fatty acid desaturase gene from variant (including mutant) plants with altered levels of unsaturated fatty acids. Sequencing of these genes will reveal nucleotide differences from the normal gene that cause the variation. Short oligonucleotides designed around these differences may also be used in molecular breeding either as hybridization probes or in DNA-based diagnostics to follow the variation in fatty acids. Oligonucleotides based on differences that are linked to the variation may be used as molecular markers in breeding these variant oil traits.

EXAMPLES

The present invention is further defined in the following Examples, in which all parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be understood that these Examples, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. All publications, including patents and non-patent literature, referred to in this specification are expressly incorporated by reference herein.

EXAMPLE 1

ISOLATION OF GENOMIC DNA FLANKING THE T-DNA SITE OF INSERTION IN ARABIDOPSIS THALIANA MUTANT LINE 658

Identification of an Arabidopsis thaliana T-DNA Mutant with High Oleic Acid Content

A population of Arabidopsis thaliana (geographic race Wassilewskija) transformants containing the modified T-DNA of Agrobacterium tumefaciens was generated by seed transformation as described by Feldmann et al., (Mol. Gen. Genetics (1987) 208:1-9). In this population the transformants contain DNA sequences encoding the pBR322 bacterial vector, nopaline synthase, neomycin phosphotransferase (NPTII, confers kanamycin resistance), and b-lactamase (confers ampicillin resistance) within the T-DNA border sequences. The integration of the T-DNA into different areas of the chromosomes of individual transformants may cause a disruption of plant gene function at or near the site of insertion, and phenotypes associated with this loss of gene function can be analyzed by screening the population for the phenotype.

T3 seed was generated from the wild type seed treated with Agrobacterium tumefaciens by two rounds of self-fertilization as described by Feldmann et al., (Science (1989) 243:1351-1354). These progeny were segregating for the T-DNA insertion, and thus for any mutation resulting from the insertion. Approximately 10-12 leaves of each of 1700 lines were combined and the fatty acid content of each of the 1700 pooled samples was determined by gas chromatography of the fatty acyl methyl esters essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H_2SO_4 in methanol was used as the methylation reagent. A line designated "658" produced a sample that gave an

alt red fatty acid profile compared to those of lines 657 and 659 sampled at the same time (Table 8).

TABLE 8

Fatty Acid Methyl Ester	657 Leaf Pool	659 Leaf Pool	658 Leaf Pool
16:0	14.4	14.1	13.6
16:1	4.4	4.6	4.5
16:2	2.9	2.2	2.7
16:3	13.9	13.3	13.9
18:0	1.0	1.1	0.9
18:1	2.6	2.5	4.9
18:2	14.0	13.6	12.8
18:3	42.9	46.1	44.4

Analysis of the fatty acid composition of 12 individual T3 seeds of line 658 indicated that the 658 pool was composed of seeds segregating in three classes: "high", "mid-range" and "low" classes with approximately 37% (12 seeds), 21% (7 seeds), and 14% (3 seeds) oleic acid, respectively (Table 9).

TABLE 9

	"High" Class	"Mid-range" Class	"Low" Class
16:0	8.9	8.7	9.3
16:1c	2.0	1.6	2.6
18:0	4.5	4.3	4.4
18:1	37.0	20.7	14.4
18:2	8.0	24.9	27.7
18:3	10.6	14.3	13.6
20:1	25.5	21.6	20.4

Thus, the high oleic acid mutant phenotype segregates in an approximately Mendelian ratio. To determine the number of independently segregating T-DNA

inserts in line 658, 200 T3 seeds were tested for their ability to germinate and grow in the presence of kanamycin [Feldman et al. (1989) Science 243:1351-1354]. In this experiment, only 4 kanamycin-sensitive individual plants were identified. The segregation ratio (approximately 50:1) indicated that line 658 harbored three T-DNA inserts. In this and two other experiments a total of 56 kanamycin-sensitive plants were identified; 53 of these were analyzed for fatty acid composition and at least seven of these displayed oleic acid levels that were higher than would be expected for wild type seedlings grown under these conditions.

In order to more rigorously test whether the mutation resulting in high oleic acid is the result of T-DNA insertion, Applicants identified a derivative line that was segregating for the mutant fatty acid phenotype as well as a single kanamycin resistance locus. For this, approximately 100 T3 plants were individually grown to maturity and seeds collected. One sample of seed from each T3 plant was tested for the ability to germinate and grow in the presence of kanamycin. In addition, the fatty acid compositions of ten additional individual seeds from each line were determined. A T3 plant, designated 658-75, was identified whose progeny seeds segregated 28 kanamycin-sensitive to 60 kanamycin-resistant and 7 with either low or intermediate oleic acid to 2 high oleic acid.

A total of approximately 400 T4 progeny seeds of the derivative line 658-75 were grown and the leaf fatty acid composition analyzed. A total of 91 plants were identified as being homozygous for the high oleic acid trait (18:2/18:1 less than 0.5). The remaining plants (18:2/18:1 more than 1.2) could not be definitively assigned to wild type and heterozygous classes on the

basis of leaf fatty acid composition and thus could not be used to test linkage between the kanamycin marker and the fatty acid mutation. Eighty three of the 91 apparently homozygous high oleic acid mutant were tested for the presence of nopaline, another T-DNA marker, in leaf extracts (Errampalli et al. The Plant Cell (1991)3:149-157 and all 83 plants were positive for the presence of nopaline. This tight linkage of the mutant fatty acid phenotype and a T-DNA marker provides evidence that the high oleic acid trait in mutant 658 is the result of T-DNA insertion.

Plasmid Rescue and Analysis

One-half and one microgram of genomic DNA from the homozygous mutant plants of the 658-75 line, prepared from leaf tissue as described [Rogers, S. O. and A. J. Bendich (1985) Plant Molecular Biology 5:69-76], was digested with 20 units of either Bam HI or Sal I restriction enzyme (Bethesda Research Laboratory) in a 50 µL reaction volume according to the manufacturer's specifications. After digestion the DNA was extracted with buffer-saturated phenol (Bethesda Research Laboratory) followed by precipitation in ethanol. One-half to one microgram of Bam HI or Sal I digested genomic DNA was resuspended in 200 uL or 400 uL of ligation buffer containing 50 mM Tris-Cl, pH 8.0, 10 mM $MgCl_2$, 10 mM dithiothreitol, 1 mM ATP, and 4 units of T4 DNA ligase (Bethesda Research Laboratory). The dilute DNA concentration of approximate 2.5 ug/mL in the ligation reaction was chosen to facilitate circularization, as opposed to intermolecular joining. The reaction was incubated for 16 h at 16°C. Competent DH10B cells (Bethesda Research Laboratory) were transfected with 10 ng of ligated DNA per 100 µL of competent cells according to the manufacturer's specifications. Transformants from Sal I or Bam HI

digests were selected on LB plates (10 g Bacto-tryptone, 5 g Bacto-yeast extract, 5 g NaCl, 15 g agar per liter, pH 7.4) containing 100 µg/mL ampicillin. After overnight incubation at 37°C the plates were scored for ampicillin-resistant colonies.

A single ampicillin-resistant transformant derived from Bam HI-digested plant DNA was used to start a culture in 35 mL LB medium (10 g Bacto-tryptone, 5 g yeast-extract, 5 g NaCl per liter) containing 25 mg/L ampicillin. The culture was incubated with shaking overnight at 37°C and the cells were then collected by centrifugation at 1000xg for 10 min. Plasmid DNA, designated p658-1, was isolated from the cells by the alkaline lysis method of Birmbiom et al. [Nucleic Acid Research (1979) 7:1513-1523], as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed (1989) Cold Spring Harbor Laboratory Press). Plasmid p658-1 DNA was digested by restriction enzymes Bam HI, Eco RI and Sal I (Bethesda Reseach Laboratory) and electrophoresed through a 1% agarose gel in 1xTBE buffer (0.089M tris-borate, 0.002M EDTA). The restriction pattern indicated the presence in this plasmid of the expected 14.2 kB T-DNA fragment and a 1.6 kB putative plant DNA/T-DNA border fragment.

EXAMPLE 2

CLONING OF ARABIDOPSIS THALIANA MICROSOMAL DELTA-12 DESATURASE cDNA USING GENOMIC DNA FLANKING THE T-DNA SITE OF INSERTION IN ARABIDOPSIS THALIANA MUTANT LINE 658-75 AS A HYBRIDIZATION PROBE

Two hundred nanograms of the 1.6 kB Eco RI-Bam HI fragment from plasmid p658-1, following digestion of the plasmid with Eco RI and Bam HI and purification by electrophoresis in agarose, was radiolabelled with alpha[32P]-dCTP using a Random Priming Labeling Kit

(Bethesda Research Laboratory) under conditions recommended by the manufacturer.

The radiolabeled DNA was used as a probe to screen an Arabidopsis cDNA library made from RNA isolated from above ground portions of various growth stages (Elledge et al., (1991) Proc. Nat. Acad. Sci., 88:1731-1735) essentially as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). For this, approximately 17,000 plaque-forming units were plated on seven 90mm petri plates containing a lawn of LE392 E. coli cells on NZY agar media (5 g NaCl, 2 g MgSO4-7 H20, 5 g yeast extract, 10 g casein acid hydrolysate, 13 g agar per liter). Replica filters of the phage plaques were prepared by adsorbing the plaques onto nitrocellulose filters (BA85, Schleicher and Schuell) then soaking successively for five min each in 0.5 M NaOH/1 M NaCl, 0.5 M Tris(pH 7.4)/1.5 M NaCl and 2xSSPE (0.36 M NaCl, 20 mM NaH2PO4(p H7.4), 20 mM EDTA (pH 7.4)). The filters were then air dried and baked for 2 h at 80°C. After baking the filters were wetted in 2X SSPE, and then incubated at 42°C in prehybridization buffer (50% Formamide, 5X SSPE, 1% SDS, 5X Denhardt's Reagent, and 100 ug/mL denatured salmon sperm DNA) for 2 h. The filters were removed from the prehybridization buffer, and then transferred to hybridization buffer (50% Formamide, 5X SSPE, 1% SDS, 1X Denhardt's Reagent, and 100 ug/mL denatured salmon sperm DNA) containing the denatured radiolabeled probe (see above) and incubated for 40 h at 42°C. The filters were washed three times in 2X SSPE/0.2% SDS at 42°C (15 min each) and twice in 0.2X SSPE/0,2% SDS at 55°C (30 min each), followed by autoradiography on Kodak XAR-5 film with an intensifying screen at -80°C, overnight. Fifteen plaques were identified as positively-

hybridizing on replica filters. Five of these were subjected to plaque purification essentially as described in Sambrook et al., (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). The lambda YES-R cDNA clones were converted to plasmid by propagating the phage in the E. coli BNN--132 cells, which expresses Cre protein that excises the cDNA insert as a double-stranded plasmid by cre-mediated in vivo site-speicifc recombination at a 'lox' sites present in the phage. Ampicillin-resistant plasmid clones containing cDNA inserts were grown in liquid culture, and plasmid DNA was prepared using the alkaline lysis method as previously described. The sizes of the resulting plasmids were analyzed by electrophoresis in agarose gels. The agarose gels were treated with 0.5 M NaOH/1 M NaCl, and 0.5 M Tris(pH 7.4), 1.5 M NaCl for 15 min each, and the gel was then dried completely on a gel drier at 65°C. The gel was hydrated in 2X SSPE and incubated overnight, at 42°C, in hybridization buffer containing the denatured radiolabeled probe, followed by washing as described above. After autoradiography, the inserts of four of the purified cDNA clones were found to have hybridized to the probe. Plasmid DNA from the hybridizing clones was purified by equilibration in a CsCl/ethidium bromide gradient (see above). The four cDNA clones were sequenced using Sequenase T7 DNA polymerase (US Biochemical Corp.) and the manufacturer's instructions, beginning with primers homologous to vector sequences that flank the cDNA insert. After comparing the partial sequences of the inserts obtained from the four clones, it was apparent that they each contained sequences in common. One cDNA clone, p92103, containing ca. 1.4 kB cDNA insert, was sequenced. The longest three clones were subcloned into the plasmid vector pBluescript

(Stratagene). One of these clones, designated pSF2b, containing ca 1.2 kB cDNA insert was also sequenced serially with primers designed from the newly acquired sequences as the sequencing experiment progressed. The composite sequence derived from pSF2b and p92103 is shown in SEQ ID NO:1.

EXAMPLE 3

CLONING OF PLANT FATTY ACID DESATURASE cDNAs USING THE ARABIDOPSIS THALIANA MICROSOMAL DELTA-12 DESATURASE cDNA CLONE AS A HYBRIDIZATION PROBE

An approximately 1.2 kb fragment containing the *Arabidopsis* delta-12 desaturase coding sequence of SEQ ID NO:1 was obtained from plasmid pSF2b. This plasmid was digested with EcoR I and the 1.2 kb delta-12 desaturase cDNA fragment was purified from the vector sequence by agarose gel electrophoresis. The fragment was radiolabelled with ^{32}P as previously described.

Cloning of a Brassica napus Seed cDNA Encoding Microsomal Delta-12 Fatty Acid Desaturase

The radiolabelled probe was used to screen a *Brassica napus* seed cDNA library. In order to construct the library, *Brassica napus* seeds were harvested 20-21 days after pollination, placed in liquid nitrogen, and polysomal RNA was isolated following the procedure of Kamalay et al., (Cell (1980) 19:935-946). The polyadenylated mRNA fraction was obtained by affinity chromatography on oligo-dT cellulose (Aviv et al., Proc. Natl. Acad. Sci. USA (1972) 69:1408-1411). Four micrograms of this mRNA were used to construct a seed cDNA library in lambda phage (Uni-ZAP™ XR vector) using the protocol described in the ZAP-cDNA™ Synthesis Kit (1991 Stratagene Catalog, Item #200400). Approximately 600,000 clones were screened for positively hybridizing

plaques using the radiolabelled EcoR I fragm nt from pSF2b as a probe essentially as described in Sambrook et al., (Molecular Cloning: A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press) except that low stringency hybridization conditions (50 mM Tris, pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 µg denatured calf thymus DNA and 50°C) were used and post-hybridization washes were performed twice with 2X SSC, 0.5% SDS at room temperature for 15 min, then twice with 0.2X SSC, 0.5% SDS at room temperature for 15 min, and then twice with 0.2X SSC, 0.5% SDS at 50°C for 15 min. Ten positive plaques showing strong hybridization were picked, plated out, and the screening procedure was repeated. From the secondary screen nine pure phage plaques were isolated. Plasmid clones containing the cDNA inserts were obtained through the use of a helper phage according to the in vivo excision protocol provided by Stratagene. Double-stranded DNA was prepared using the alkaline lysis method as previously described, and the resulting plasmids were size-analyzed by electrophoresis in agarose gels. The largest one of the nine clones, designated pCF2-165D, contained an approximately 1.5 kb insert which was sequenced as described above. The sequence of 1394 bases of the cDNA insert of pCF2-165D is shown in SEQ ID NO:3. Contained in the insert but not shown in SEG ID NO:3 are approximately 40 bases of the extreme 5' end of the 5' non-translated region and a poly A tail of about 38 bases at the extreme 3' end of the insert.

Cloning of a Soybean Seed cDNA Encoding Microsomal Delta-12 Fatty Acid Desaturase

A cDNA library was made as follows: Soybean embryos (ca. 50 mg fresh weight each) were removed from the pods and frozen in liquid nitrogen. The frozen

embryos were ground to a fine powder in the presence of liquid nitrogen and then extracted by Polytron homogenization and fractionated to enrich for total RNA by the method of Chirgwin et al. (Biochemistry (1979) 18:5294-5299). The nucleic acid fraction was enriched for poly A$^+$RNA by passing total RNA through an oligo-dT cellulose column and eluting the poly A$^+$RNA with salt as described by Goodman et al. (Meth. Enzymol. (1979) 68:75-90). cDNA was synthesized from the purified poly A$^+$RNA using cDNA Synthesis System (Bethesda Research Laboratory) and the manufacturer's instructions. The resultant double-stranded DNA was methylated by Eco RI DNA methylase (Promega) prior to filling-in its ends with T4 DNA polymerase (Bethesda Research Laboratory) and blunt-end ligation to phosphorylated Eco RI linkers using T4 DNA ligase (Pharmacia). The double-stranded DNA was digested with Eco RI enzyme, separated from excess linkers by passage through a gel filtration column (Sepharose CL-4B), and ligated to lambda ZAP vector (Stratagene) according to manufacturer's instructions. Ligated DNA was packaged into phage using the Gigapack packaging extract (Stratagene) according to manufacturer's instructions. The resultant cDNA library was amplified as per Stratagene's instructions and stored at -80°C.

Following the instructions in the Lambda ZAP Cloning Kit Manual (Stratagene), the cDNA phage library was used to infect _E. coli_ BB4 cells and approximately 600,000 plaque forming units were plated onto 150 mm diameter petri plates. Duplicate lifts of the plates were made onto nitrocellulose filters (Schleicher & Schuell). The filters were prehybridized in 25 mL of hybridization buffer consisting of 6X SSPE, 5X Denhardt's solution, 0.5% SDS, 5% dextran sulfate and 0.1 mg/mL denatured salmon sperm DNA (Sigma Chemical

Co.) at 50°C for 2 h. Radiolabelled probe prepared from pSF2b as described above was added, and allowed to hybridize for 18 h at 50°C. The filters were washed exactly as described above. Autoradiography of the filters indicated that there were 14 strongly hybridizing plaques. The 14 plaques were subjected to a second round of screening as before. Numerous, strongly hybridizing plaques were observed on 6 of the 14 filters, and one, well-isolated from other phage, was picked from each of the six plates for further analysis.

Following the Lambda ZAP Cloning Kit Instruction Manual (Stratagene), sequences of the pBluescript vector, including the cDNA inserts, from the purified phages were excised in the presence of a helper phage and the resultant phagemids were used to infect E. coli XL-1 Blue cells. DNA from the plasmids was made by the Promega "Magic Miniprep" according to the manufacturers instructions. Restriction analysis indicated that the plasmids contained inserts ranging in size from 1 kb to 2.5 kb. The alkali-denatured double-stranded DNA from one of these, designated pSF2-169K contained an insert of 1.6 kb, was sequenced as described above. The nucleotide sequence of the cDNA insert in plasmid pSF2-169K shown in SEQ ID NO:5.

Cloning of a Corn (Zea mays)
cDNA Encoding Seed Microsomal Delta-12
Fatty Acid Desaturase

Corn microsomal delta-12 desaturase cDNA was isolated using a PCR approach. For this, a cDNA library was made to poly A^+ RNA from developing corn embryos in Lambda ZAP II vector (Stratagene). 5-10 ul of this library was used as a template for PCR using 100 pmol each of two sets of degenerate oligomers NS3 (SEQ ID NO:13) and equimolar amounts of RB5a/b (that is, equimolar amounts of SEQ ID NOS:16/17) as sense and

antisense primers, respectively. NS3 and RB5a/b correspond to stretches of amino acids 101-109 and 318-326, respectively, of SEQ ID NO:2, which are conserved in most microsomal delta-12 desaturases (SEQ ID NOS:2, 4, 6, 8). PCR was carried out using the PCR kit (Perkin-Elmer) using 40 cycles of 94°C 1 min, 45°C, 1 min, and 55°C, 2 min. Analyses of the PCR products on an agarose gel showed the presence of a product of the expected size (720 bp), which was absent in control reactions containing either the sense or antisense primers alone. The PCR product fragment was gel purified and then used as a probe for screening the same corn cDNA library at 60°C as described above. One positively-hybridizing plaque was purified and partial sequence determination of its cDNA showed it to be a nucleotide sequence encoding microsomal delta-12 desaturase but truncated at the 3' end. The cDNA insert encoding the partial desaturase was gel isolated and used to probe the corn cDNA library again. Several positive plaques were recovered and characterized. DNA sequence analysis revealed that all of these clones seem to represent the same sequence with the different length of 5' or 3' ends. The clone containing the longest insert, designated pFad2#1, was sequenced completely. SEQ ID NO:7 shows the 5' to 3' nucleotide sequence of 1790 base pairs of corn (Zea mays) cDNA which encodes microsomal delta-12 desaturase in plasmid pFad2#1. Nucleotides 165 to 167 and nucleotides 1326 to 1328 are, respectively, the putative initiation codon and the termination codon of the open reading frame (nucleotides 164 to 1328). SEQ ID NO:8 is the 387 amino acid protein sequence deduced from the open reading frame (nucleotides 164 to 1328) in SEQ ID NO:7. The deduced amino acid sequence of the polypeptide shared overall identities of 71%, 40%, and 38% to Arabidopsis

microsomal delta-12 desaturase, Arabidopsis microsomal delta-15 desaturase, and Arabidopsis plastid delta-15 desaturase, respectively. Furthermore, it lacked an N-terminal amino acid extension that would indicate it is a plastid enzyme. Based on these considerations, it is concluded that it encodes a microsomal delta-12 desaturase.

Cloning of a cDNA Encoding A Microsomal Delta-12 Desaturase and of cDNAs Encoding Microsomal Delta-12 Desaturase-Related Enzymes from Castor Bean Seed

Castor microsomal delta-12 desaturase cDNA was isolated using a RT-PCR approach. Polysomal mRNA was isolated from castor beans of stages I-II (5-10 DAP) and also from castor beans of stages IV-V (20-25 DAP). Ten ng of each mRNA was used for separate RT-PCR reactions, using the Perkin-Elmer RT-PCR kit with the reagent concentration as recommended by the kit protocol. The reverse transcriptase reaction was primed with random hexamers and the PCR reaction with 100 pmol each of the degenerate delta-12 desaturase primers NS3 and NS9 (SEQ ID NOS:13 and 14, respectively). The reverse transcriptase reaction was incubated at 25°C for 10 min, 42°C for 15 min, 99°C for 5 min and 5°C for 5 min. The PCR reaction was incubated at 95°C for 2 min followed by 35 cycles of 95°C for 1 min/50°C for 1 min. A final incubation at 60°C for 7 min completed the reaction. A DNA fragment of 720 bp was amplified from both stage I-II and stage IV-V mRNA. The amplified DNA fragment from one of the reactions was gel purified and cloned into a pGEM-T vector using the Promega pGEM-T PCR cloning kit to create the plasmid pRF2-1C. The 720 bp insert in pRF2-1C was sequenced, as described above, and the resulting DNA sequence is shown in SEQ ID NO:9. The DNA sequence in SEQ ID NO:9 contains an open-reading frame encoding 219 amino acids (SEQ ID NO:10), which has

81% identity (90% similarity) with amino acids 135 to 353 of the _Arabidopsis_ microsomal delta-12 desaturase described in SEQ ID NO:2. The cDNA insert in pRF2-1C is therefore a 673 bp fragment of a full-length cDNA encoding a castor bean seed microsomal delta-12 desaturase. The full length castor bean seed microsomal delta-12 desaturase cDNA may isolated by screening a castor seed cDNA library, at 60°C, with the labeled insert of pRF2-1C as described in the example above. The insert in pRF2-1C may also be used to screen castor bean libraries at lower temperatures to isolate delta-12 desaturase related sequences, such as the delta-12 hydroxylase.

A cDNA library made to poly A^+ mRNA isolated from developing castor beans (stages IV-V, 20-25 DAP) was screened as described above. Radiolabeled probe prepared from pSF2b or pRF2-1C, as described above, were added, and allowed to hybridize for 18 h at 50°C. The filters were washed as described above. Autoradiography of the filters indicated that there were numerous hybridizing plaques, which appeared either strongly hybridising or weakly hybridising. Three of the strongly hybridisng plaques (190A-41, 190A-42 and 190A-44) and three of the weakly hybridising plaques, (190B-41, 190b-43 and 197c-42), were plaque purified using the methods described above. The cDNA insert size of the purified phages were determined by PCR amplication of the insert using phage as template and lambda-gt11 oligomers (Clontech lambda-gt11 Amplimers) for primers. The PCR-amplified inserts of the amplified phages were subcloned into pBluescript (Pharmacia) which had been cut with Eco RI and filled in with Klenow (Sambrook et al. (Molecular Cloning, A Laboratory Approach, 2nd. ed. (1989) Cold Spring Harbor Laboratory Press). The resulting plasmids were called pRF190a-41,

pRF190a-42, pRF190a-44, pRF190b-41, pRF190b-43 and pRF197c-42. All of the inserts were about 1.1 kb with the exception of pRF197c-42 which was approx. 1.5 kb. The inserts in the plasmids were sequenced as described above. The insert in pRF190b-43 did not contain any open reading frame and was not identified. The inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 were identical. The insert in pRF197c-42 contained all of the nucleotides of the inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 plus an additional approx. 400 bp. It was deduced therefore that the insert in pRF197c-42 was a longer version of the inserts in pRF190a-41, pRF190a-42, pRF190a-44 and pRF190b-41 and all were derived from the same full-length mRNA. The complete cDNA sequence of the insert in plasmid pRF197c-42 is shown in SEQ ID NO:11. The deduced amino acid sequence of SEQ ID NO:11, shown in SEQ ID NO:12, is 78.5% identical (90% similarity) to the castor microsomal delta-12 desaturase described above (SEQ ID NO:10) and 66% identical (80% similarity) to the Arabidopsis delta-12 desaturase amino acid sequence in SEQ ID NO:2. These similarities confirm that pRF197c-42 is a castor bean seed cDNA that encodes a microsomal delta-12 desaturase or a microsomal delta-12 desaturase-related enzyme, such as a delta-12 hydroxylase. Specific PCR primers for pRF2-1C and pRF197c-42 were made. For pRF2-1c the upstream primer was bases 180 to 197 of the cDNA sequence in SEQ ID NO:9. For pRF197c-42 the upstream primer was bases 717 to 743 of the cDNA sequence in SEQ ID NO:11. A common downstream primer was made corresponding to the exact complement of the nucleotides 463 to 478 of the sequence described in SEQ ID NO:9. Using RT-PCR with random hexamers and the above primers, and the incubation temperatures described above, it was observed that mRNA which gave rise to the

cDNA contained in pRF2-1C is present in both Stage I-II and Stage IV-V castor bean seeds whereas mRNA which gave rise to the cDNA contained in plasmid pRF197c-42 is present only in Stage IV-V castor bean seeds, i.e., it is only expressed in tissue actively synthesizing ricinoleic acid. Thus it is possible that this cDNA encodes a delta-12 hydroxylase.

Clones such as pRF2-1C and pRF197c-42, and other clones from the differential screening, which, based on their DNA sequence, are less related to castor bean seed microsomal delta-12 desaturases and are not any of the known fatty-acid desaturases described above or in WO 9311245, may be expressed, for example, in soybean embryos or another suitable plant tissue, or in a microorganism, such as yeast, which does not normally contain ricinoleic acid, using suitable expression vectors and transformation protocols. The presence of novel ricinoleic acid in the transformed tissue(s) expressing the castor cDNA would confirm the identity of the castor cDNA as DNA encoding for an oleate hydroxylase.

EXAMPLE 4

USE OF THE ARABIDOPSIS THALIANA DELTA-12 DESATURASE GENOMIC CLONE AS A RESTRICTION FRAGMENT LENGTH POLYMORPHISM (RFLP) MARKER TO MAP THE DELTA-12 DESATURASE LOCUS IN ARABIDOPSIS

The gene encoding *Arabidopsis* microsomal delta-12 desaturase was used to map the genetic locus encoding the microsomal delta-12 desaturase of *Arabidopsis thaliana*. pSF2b cDNA insert encoding *Arabidopsis* microsomal delta-12 desaturase DNA was radiolabeled and used to screen an *Arabidopsis* genomic DNA library. DNA from several pure strongly-hybridizing phages was isolated. Southern blot analysis of the DNA from different phages using radiolabeled pSF2b cDNA insert as

the probe identified a 6 kb Hind III insert fragment to contain the coding region of the gene. This fragment was subcloned in pBluescript vector to result in plasmid pAGF2-6 and used for partial sequence determination. This sequence (SEQ ID NO:15) confirmed that it is the microsomal delta-12 desaturase gene. DNA from two phages was isolated and labelled with ^{32}P using a random priming kit from Pharmacia under conditions recommended by the manufacturer. The radioactive DNA was used to probe a Southern blot containing genomic DNA from Arabidopsis thaliana (ecotype Wassileskija and marker line W100 ecotype Landesberg background) digested with one of several restriction endonucleases. Following hybridization and washes under standard conditions (Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd ed. (1989) Cold Spring Harbor Laboratory Press), autoradiograms were obtained. A different pattern of hybridization (polymorphism) was identified in Hind III-digested genomic DNAs using one of the phage DNAs. This polymorphism was located to a 7 kB Hind III fragment in the phage DNA that revealed the polymorphism. The 7 kb fragment was subcloned in pBluescript vector to result in plasmid pAGF2-7. Plasmid pAGF2-7 was restricted with Hind III enzyme and used as a radiolabelled probe to map the polymorphism essentially as described by Helentjaris et al., (Theor. Appl. Genet. (1986) 72:761-769). The radiolabelled DNA fragment was applied as described above to Southern blots of Hind III-digested genomic DNA isolated from 117 recombinant inbred progeny (derived from single-seed descent lines to the F_6 generation) resulting from a cross between Arabidopsis thaliana marker line W100 and ecotype Wassileskija (Burr et al., Genetics (1988) 118:519-526). The bands on the autoradiograms were interpreted as resulting from inheritance of either

pat rnal (ecotype Wassileskija) or maternal (marker line W100) DNA or both (a heterozygote). The resulting segregation data were subjected to genetic analysis using the computer program Mapmaker (Lander et al., Genomics (1987) 1:174-181). In conjunction with previously obtained segregation data for 63 anonymous RFLP markers and 9 morphological markers in Arabidopsis thaliana (Chang et al., Proc. Natl. Acad. Sci. USA (1988) 85:6856-6860; Nam et al., Plant Cell (1989) 1:699-705), a single genetic locus was positioned corresponding to the microsomal delta-12 desaturase gene. The location of the microsomal delta-12 desaturase gene was thus determined to be 13.6 cM proximal to locus c3838, 9.2 cM distal to locus 1At228, and 4.9 cM proximal to FadD locus on chromosome 3 [Koorneef, M. et. al. (1993) in Genetic Maps, Ed. O'Brien, S. J.; Yadav et al. (1993) Plant Physiology 103:467-476.]

EXAMPLE 5

USE OF SOYBEAN MICROSOMAL DELTA-12 DESATURASE cDNA SEQUENCE AS A RESTRICTION FRAGMENT LENGTH POLYMORPHISM (RFLP) MARKER

The 1.6 kb insert obtained from the plasmid pSF2-169K as previously described was radiolabelled with ^{32}P using a Random Priming Kit from Bethesda Research Laboratories under conditions recommended by the manufacturer. The resulting radioactive probe was used to probe a Southern blot (Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd Ed. (1989) Cold Spring Harbor Laboratory Press) containing genomic DNA from soybean (Glycine max (cultivar Bonus) and Glycine soja (PI81762)) digested with one of several restriction enzymes. After hybridization and washes under low stringency conditions (50 mM Tris, pH 7.5, 6X SSPE, 10% dextran sulfate, 1% SDS at 56°C for the hybridization

and initial washes, changing to 2X SSPE and 0.1% SDS for the final wash), autoradiograms were obtained, and different patterns of hybridization (polymorphisms) were identified in digests performed with restriction enzymes Hind III and Eco RI. These polymorphisms were used to map two pSF2-169k loci relative to other loci on the soybean genome essentially as described by Helentjaris et al., (Theor. Appl. Genet. (1986) 72:761-769). The map positions of the polymorphisms were determined to be in linkage group 11 between 4404.00 and 1503.00 loci (4.5 cM and 7.1 cM from 4404.00 and 1503.00, respectively) and linkage group 19 between 4010.00 and 5302.00 loci (1.9 cM and 2.7 cM from 4010.00 and 5302.00, respectively) [Rafalski, A. and Tingey, S. (1993) in Genetic Maps, Ed. O' Brien, S. J.].

EXAMPLE 6

EXPRESSION OF MICROSOMAL DELTA-12 DESATURASE IN SOYBEANS

Construction of Vectors for Transformation of *Glycine max* for Reduced Expression of Microsomal Delta-12 Desaturases in Developing Soybean Seeds

Plasmids containing the antisense *G. max* microsomal delta-12 desaturase cDNA sequence under control of the soybean Kunitz Trypsin Inhibitor 3 (KTi3) promoter (Jofuku and Goldberg, Plant Cell (1989) 1:1079-1093) , the *Phaseolus vulgaris* 7S seed storage protein (phaseolin) promoter(Sengupta-Gopalan et al., Proc. Natl. Acad. Sci. USA (1985) 82:3320-3324; Hoffman et al., Plant Mol. Biol. (1988) 11:717-729) and soybean beta-conglycinin promoter (Beachy et al., EMBO J. (1985) 4:3047-3053), were constructed. The construction of vectors expressing the soybean delta-12 desaturase antisense cDNA under the control of these promoters was facilitated by the use of the following plasmids: pML70, pCW108 and pCW109A.

The pML70 vector contains the KTi3 promoter and the KTi3 3' untranslated region and was derived from the commercially available vector pTZ18R (Pharmacia) via the intermediate plasmids pML51, pML55, pML64 and pML65. A 2.4 kb Bst BI/Eco RI fragment of the complete soybean KTi3 gene (Jofuku and Goldberg (1989) Plant Cell 1:1079-1093), which contains all 2039 nucleotides of the 5' untranslated region and 390 bases of the coding sequence of the KTi3 gene ending at the Eco RI site corresponding to bases 755 to 761 of the sequence described in Jofuku et al (1989) Plant Cell 1:427-435, was ligated into the Acc I/Eco RI sites of pTZ18R to create the plasmid pML51. The plasmid pML51 was cut with Nco I, filled in using Klenow, and religated, to destroy an Nco I site in the middle of the 5' untranslated region of the KTi3 insert, resulting in the plasmid pML55. The plasmid pML55 was partially digested with Xmn I/Eco RI to release a 0.42 kb fragment, corresponding to bases 732 to 755 of the above cited sequence, which was discarded. A synthetic Xmn I/Eco RI linker containing an Nco I site, was constructed by making a dimer of complementary synthetic oligonucleotides consisting of the coding sequence for an Xmn I site (5'-TCTTCC-3') and an Nco I site (5'-CCATGGG-3') followed directly by part of an Eco RI site (5'-GAAGG-3'). The Xmn I and Nco I/Eco RI sites were linked by a short intervening sequence (5'-ATAGCCCCCCAA-3'). This synthetic linker was ligated into the Xmn I/Eco RI sites of the 4.94 kb fragment to create the plasmid pML64. The 3' untranslated region of the KTi3 gene was amplified from the sequence described in Jofuku et al (Ibid.) by standard PCR protocols (Perkin Elmer Cetus, GeneAmp PCR kit) using the primers ML51 and ML52. Primer ML51 contained the 20 nucleotides corresponding to bases 1072 to 1091 of the above cited

sequence with the addition of nucl otides corresponding to Eco RV (5-'GATATC-3'), Nco I (5'-CCATGG-3'), Xba I (5'-TCTAGA-3'), Sma I (5'-CCCGGG-3') and Kpn I (5'-GGTACC-3') sites at the 5' end of the primer. Primer ML52 contained to the exact compliment of the nucleotides corresponding to bases 1242 to 1259 of the above cited sequence with the addition of nucleotides corresponding to Sma I (5'-CCCGGG-3'), Eco RI (5'-GAATTC-3'), Bam HI (5'-GGATCC-3') and Sal I (5'-GTCGAC-3') sites at the 5' end of the primer. The PCR-amplified 3' end of the KTi3 gene was ligated into the Nco I/Eco RI sites of pML64 to create the plasmid pML65. A synthetic multiple cloning site linker was constructed by making a dimer of complementary synthetic oligonucleotides consisting of the coding sequence for Pst I (5'-CTGCA-3'), Sal I (5'-GTCGAC-3'), Bam HI (5'-GGATCC-3') and Pst I (5'-CTGCA-3') sites. The linker was ligated into the Pst I site (directly 5' to the KTi3 promoter region) of pML65 to create the plasmid pML70.

The 1.46 kb Sma I/Kpn I fragment from pSF2-169K (soybean delta-12 desaturase cDNA described above) was ligated into the corresponding sites in pML70 resulting in the plasmid pBS10. The desaturase cDNA fragment was in the reverse (antisense) orientation with respect to the KTi3 promoter in pBS10. The plasmid pBS10 was digested with Bam HI and a 3.47 kb fragment, representing the KTi3 promoter/antisense desaturase cDNA/KTi3-3' end transcriptional unit was isolated by agarose gel electrophoresis. The vector pML18 consists of the non-tissue specific and constitutive cauliflower mosaic virus (35S) promoter (Odell et al., Nature (1985) 313:810-812; Hull et al., Virology (1987) 86:482-493), driving expression of the neomycin phosphotransferase gene described in (Beck et al. (1982) Gene 19:327-336)

followed by the 3' end of the nopaline synthase gene including nucleotides 848 to 1550 described by (Depicker et al. (1982) J. Appl. Genet. 1:561-574). This transcriptional unit was inserted into the commercial cloning vector pGEM9Z (Gibco-BRL) and is flanked at the 5' end of the 35S promoter by the restriction sites Sal I, Xba I, Bam HI and Sma I in that order. An additional Sal I site is present at the 3' end of the NOS 3' sequence and the Xba I, Bam HI and Sal I sites are unique. The 3.47 kb transcriptional unit released from pBS10 was ligated into the Bam HI site of the vector pML18. When the resulting plasmids were double digested with Sma I and Kpn I, plasmids containing inserts in the desired orientation yielded 3 fragments of 5.74, 2.69 and 1.46 kb. A plasmid with the transcriptional unit in the correct orientation was selected and was designated pBS13.

The pCW108 vector contains the bean phaseolin promoter and 3' untranslated region and was derived from the commercially available pUC18 plasmid (Gibco-BRL) via plasmids AS3 and pCW104. Plasmid AS3 contains 495 base pairs of the bean (Phaseolus vulgaris) phaseolin (7S seed storage protein) promoter starting with 5'-TGGTCTTTTGGT-3' followed by the entire 1175 base pairs of the 3' untranslated region of the same gene (see sequence descriptions in Doyle et al., (1986) J. Biol. Chem. 261:9228-9238 and Slightom et al.,(1983) Proc. Natl. Acad. Sci. USA, 80:1897-1901. Further sequence description may be found in WO 9113993) cloned into the Hind III site of pUC18. The additional cloning sites of the pUC18 multiple cloning region (Eco RI, Sph I, Pst I and Sal I) were removed by digesting with Eco RI and Sal I, filling in the ends with Klenow and religating to yield the plasmid pCW104. A new multiple cloning site was created between the 495bp of the 5'

phaseolin and the 1175bp of the 3' phaseolin by inserting a dimer of complementary synthetic oligonucleotides consisting of the coding sequence for a Nco I site (5'-CCATGG-3') followed by three filler bases (5'-TAG-3'), the coding sequence for a Sma I site (5'-CCCGGG-3'), the last three bases of a Kpn I site (5'-TAC-3'), a cytosine and the coding sequence for an Xba I site (5'-TCTAGA-3') to create the plasmid pCW108. This plasmid contains unique Nco I, Sma I, Kpn I and Xba I sites directly behind the phaseolin promoter. The 1.4 kb Eco RV/Sma I fragment from pSF2-169K was ligated into the Sma I site of the commercially available phagemid pBC SK+ (Stratagene). A phagemid with the cDNA in the desired orientation was selected by digesting with Pfl MI/Xho I to yield fragments of approx. 1 kb and 4 kb and designated pM1-SF2. The 1.4 kb Xmn I/Xba I fragment from pM1-SF2 was inserted into the Sma I/Xba I sites of pCW108 to yield the plasmid pBS11, which has the soybean delta-12 desaturase cDNA in the reverse (3'-5') orientation behind the phaseolin promoter. The plasmid pBS11 was digested with Bam HI and a 3.07 kb fragment, representing the phaseolin promoter/antisense desaturase cDNA/phaseolin 3' end transcriptional unit was isolated by agarose gel electrophoresis and ligated into the Hind III site of pML18 (described above). When the resulting plasmids were digested with Xba I, plasmids containing inserts in the desired orientation yielded 2 fragments of 8.01 and 1.18 kb. A plasmid with the transcriptional unit in the correct orientation was selected and was designated pBS14.

The vector pCW109A contains the soybean b-conglycinin promoter sequence and the phaseolin 3' untranslated region and is a modified version of vector pCW109 which was derived from the commercially available plasmid pUC18 (Gibco-BRL). The vector pCW109 was made

by inserting into the Hind III site of the cloning vector pUC18 a 555 bp 5' non-coding region (containing the promoter region) of the b-conglycinin gene followed by the multiple cloning sequence containing the restriction endonuclease sites for Nco I, Sma I, Kpn I and Xba I, as described for pCW108 above, then 1174 bp of the common bean phaseolin 3' untranslated region into the Hind III site (described above). The b-conglycinin promoter region used is an allele of the published b-conglycinin gene (Doyle et al., J. Biol. Chem. (1986) 261:9228-9238) due to differences at 27 nucleotide positions. Further sequence description of this gene may be found in Slightom (WO 9113993). To facilitate use in antisense constructions, the Nco I site and potential translation start site in the plasmid pCW109 was destroyed by digestion with Nco I, mung bean exonuclease digestion and re-ligation of the blunt site to give the modified plasmid pCW109A. The plasmid pCW109A was digested with Hind III and the resulting 1.84 kb fragment, which contained the b-conglycinin/ antisense delta-12 desaturase cDNA/phaseolin 3' untranslated region, was gel isolated. The plasmid pML18 (described above) was digested with Xba I, filled in using Klenow and religated, in order to remove the Xba I site. The resulting plasmid was designated pBS16. The 1.84 kb fragment of plasmid pCW109A (described above) was ligated into the Hind III site of pBS16. A plasmid containing the insert in the desired orientation yielded a 3.53 kb and 4.41 kb fragment when digested with Kpn I and this plasmid was designated pCST2. The Xmn I/Xba I fragment of pML1-SF2 (described above) was ligated into the Sma I/Xba I sites of pCST2 to yield the vector pST11.

Transformation Of Somatic Soybean Embryo Cultures and Regeneration Of Soybean Plants

Soybean embryogenic suspension cultures were maintained in 35 mL liquid media (SB55 or SBP6) on a rotary shaker, 150 rpm, at 28°C with mixed florescent and incandescent lights on a 16:8 h day/night schedule. Cultures were subcultured every four weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

Soybean embryogenic suspension cultures were transformed with pCS3FdST1R by the method of particle gun bombardment (see Kline et al. (1987) Nature (London) 327:70). A DuPont Biolistic PDS1000/HE instrument (helium retrofit) was used for these transformations.

To 50 mL of a 60 mg/mL 1 mm gold particle suspension was added (in order); 5 uL DNA(1 ug/uL), 20 uL spermidine (0.1 M), and 50 ul $CaCl_2$ (2.5 M). The particle preparation was agitated for 3 min, spun in a microfuge for 10 sec and the supernatant removed. The DNA-coated particles were then washed once in 400 uL 70% ethanol and re suspended in 40 uL of anhydrous ethanol. The DNA/particle suspension was sonicated three times for 1 sec each. Five uL of the DNA-coated gold particles were then loaded on each macro carrier disk.

Approximately 300-400 mg of a four week old suspension culture was placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue were normally bombarded. Membrane rupture pressure was set at 1000 psi and the chamber was evacuated to a vacuum of 28 inches of mercury. The tissue was placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the

tissue was placed back into liquid and cultured as described above.

Eleven days post bombardment, the liquid media was exchanged with fresh SB55 containing 50 mg/mL hygromycin. The selective media was refreshed weekly. Seven weeks post bombardment, green, transformed tissue was observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue was removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Thus each new line was treated as independent transformation event. These suspensions can then be maintained as suspensions of embryos clustered in an immature developmental stage through subculture or regenerated into whole plants by maturation and germination of individual somatic embryos.

Transformed embryogenic clusters were removed from liquid culture and placed on a solid agar media (SB103) containing no hormones or antibiotics. Embryos were cultured for eight weeks at 26°C with mixed florescent and incandescent lights on a 16:8 h day/night schedule. During this period, individual embryos were removed from the clusters and analyzed at various stages of embryo development After eight weeks somatic embryos become suitable for germination. For germination, eight week old embryos were removed from the maturation medium and dried in empty petri dishes for 1 to 5 days. The dried embryos were then planted in SB71-1 medium were they were allowed to germinate under the same lighting and germination conditions described above. Germinated embryos were transferred to sterile soil and grown to maturity for seed collection.

Analysis Of Transgenic Glycine Max Embryos and Seeds Containing An Antisense Delta-15 Desaturase: Demonstration That The Phenotype Of Transgenic Soybean Somatic Embryos Is Predictive Of The Phenotype Of Seeds Derived From Plants Regenerated From Those Embryos

While in the globular embryo state in liquid culture as described above, somatic soybean embryos contain very low amounts of triacylglycerol or storage proteins typical of maturing, zygotic soybean embryos. At this developmental stage, the ratio of total triacylglyceride to total polar lipid (phospholipids and glycolipid) is about 1:4, as is typical of zygotic soybean embryos at the developmental stage from which the somatic embryo culture was initiated. At the globular stage as well, the mRNAs for the prominent seed proteins (alpha' subunit of beta-conglycinin, Kunitz Trypsin Inhibitor 3 and Soybean Seed Lectin) are essentially absent. Upon transfer to hormone free media to allow differentiation to the maturing somatic embryo state as described above, triacylglycerol becomes the most abundant lipid class. As well, mRNAs for alpha'-subunit of beta-conglycinin, Kunitz Trypsin Inhibitor 3 and Soybean Seed Lectin become very abundant messages in the total mRNA population. In these respects the somatic soybean embryo system behaves very similarly to maturing zygotic soybean embryos in vivo, and is therefore a good and rapid model system for analyzing the phenotypic effects of modifying the expression of genes in the fatty acid biosynthesis pathway. Furthermore, the model system is predictive of the fatty acid composition of seeds from plants derived from transgenic embryos. Liquid culture globular embryos transformed with a vector containing a soybean microsomal delta-15 desaturase, in a reverse orientation and under the control of soybean conglycinin promoter

(pCS3FdST 1R), gave rise to mature embryos with a reduced 18:3 content (WO 9311245). A number of embryos from line A2872 (control tissue transformed with pCST) and from lines 299/1/3, 299/15/1, 303/7/1, 306/3/1, 306/4/3, 306/4/5 (line 2872 transformed with plasmid pCS3FdST1R) were analyzed for fatty acid content. Fatty acid analysis was performed as described in WO 9311245 using single embryos as the tissue source. Mature, somatic embryos from each of these lines were also regenerated into soybean plants by transfer to regeneration medium as described above. A number of seeds taken from plants regenerated from these embryo lines were analyzed for fatty acid content. The relative fatty-acid composition of embryos taken from tissue transformed with pCS3FdST1R was compared with relative fatty-acid composition of seeds taken from plants derived from embryos transformed with pCS3FdST1R. Also, relative fatty acid compositions of embryos and seeds transformed with pCS3FdST1R were compared with control tissue, transformed with pCST. In all cases where a reduced 18:3 content was seen in a transgenic embryo line, compared with the control, a reduced 18:3 content was also observed in segregating seeds of plants derived from that line, when compared with the control seed (Table 11).

TABLE 11

Antisense Delta-15 Desaturase:
Relative 18:3 Content Of Embryos And Seeds Of Control (A2172) And Transgenic (299-, 303-, 306-) Soybean Lines

Soybean Line	Embryo	Embryo	Seed	Seed
	av.%18:3	lowest %18:3	av.%18:3*	lowest %18:3
A2872 (control)	12.1 (2.6)	8.5	8.9 (0.8)	8.0
299/1/3	5.6 (1.2)	4.5	4.3 (1.6)	2.5
299/15/1	8.9 (2.2)	5.2	2.5 (1.8)	1.4

303/7/1	7.3 (1.1)	5.9	4.9 (1.9)	2.8
306/3/1	7.0 (1.9)	5.3	2.4 (1.7)	1.3
306/4/3	8.5 (1.9)	6.4	4.5 (2.2)	2.7
306/4/5	7.6 (1.6)	5.6	4.6 (1.6)	2.7

*Seeds which were segregating with wild-type phenotype and without a copy of the transgene are not included in these averages. The number in brackets is S.D., n=10.

Thus the Applicants conclude that an altered polyunsaturated fatty acid phenotype observed in a transgenic, mature somatic embryo line is predictive of an altered fatty acid composition of seeds of plants derived from that line.

<u>Analysis Of Transgenic Glycine Max Embryos Containing An Antisense Microsomal Delta-12 Desaturase Construct</u>

The vectors pBS13, pBS14 and pST11 contain the soybean microsomal delta-12 desaturase cDNA, in the antisense orientation, under the control of the soybean Kunitz Trypsin Inhibitor 3 (KTi3), <u>Phaseolus</u> phaseolin, and soybean beta-conglycinin promoters as described above. Liquid culture globular embryos transformed with vectors pBS13, pBS14 and pST11, gave rise to mature embryo lines as described above. Fatty acid analysis was performed as described in WO 9311245 using single, mature embryos as the tissue source. A number of embryos from line A2872 (control tissue transformed with pCST) and from line A2872 transformed with vectors pBS13, pBS14 and pST11 were analyzed for fatty acid content. About 30% of the transformed lines showed an increased 18:1 content when compared with control lines transformed with pCST described above, demonstrating that the delta-12 desaturase had been inhibited in these lines. The remaining transformed lines showed relative fatty acid compositions similar to those of the control line. The relative 18:1 content of the lines showing an increased 18:1 content was as high as 50% compared with

a maximum of 12.5% in the control embryo lines. The average 18:1 content of embryo lines which showed an increased 18:1 content was about 35% (Table 11). In all the lines showing an increased 18:1 content there was a proportional decrease in the relative 18:2 content (Table 12). The relative proportions of the other major fatty acids (16:0, 18:0 and 18:3) were similar to those of the control.

TABLE 12

Summary Of Experiment In Which Soybean Embryos Were Transformed With Plasmids Containing A Soybean Antisense Microsomal Delta-12 Desaturase cDNA

		# of lines		
	# of Vector Lines	with high 18:1	highest 18:1	av. (%) 18:1
pCST (control)	---	---	12.5	10.5
pBS13	11	4	53.5	35.9
pBS14	11	2	48.7	32.6
pST11	11	3	50.1	35.9

In Table 12 the average 18:1 of transgenics is the average of all embryos transformed with a particular vector whose relative 18:1 content is greater than two standard deviations from the highest control value (12.5). The control average is the average of ten A2872 embryos (standard deviation = 1.2). The data in Table 12 are derived from Table 13 below.

2	15.8	2.8	37.7	26.9	14.8
3	17.3	3.4	23.3	37.9	16.0

N.B. All other transformed embryos (24 lines) had fatty acid profiles similar to those of the control.

One of these embryo lines, G335/1/25, had an average 18:2 content of less than 20% and an average 18:1 content greater than 45% (and as high as 53.5%). The Applicants expect, based on the data in table ?, that seeds derived from plants regenerated from such lines will have an equivalent or greater increase in 18:1 content and an equivalent or greater increase decrease in 18:2 content.

EXPRESSION OF MICROSOMAL DELTA-12 DESATURASE IN CANOLA

Construction Of Vectors For Transformation of Brassica Napus For Reduced Expression of Microsomal Delta-12 Desaturases in Developing Canola Seeds

An extended poly A tail was removed from the canola delta-12 desaturase sequence contained in plasmid pCF2-165D and additional restriction sites for cloning were introduced as follows. A PCR primer was synthesized corresponding to bases 354 through 371 of SEQ ID NO:3. The second PCR primer was synthesized as

the complement to bases 1253 through 1231 with 15 additional bases (GCAGATATCGCGGCC) added to the 5' end. The additonal bases encode both an EcoRV site and a NotI site. pCF2-165D was used as the template for PCR amplification using these primers. The 914 base pair product of PCR amplification was digested with EcoRV and PflMI to give an 812 base pair product corresponding to bases 450 through 1253 of pCF2-165D with the added NotI site.

pCF2-165D was digested with PstI, the PstI overhang was blunted with Klenow fragment and then digested with PflMI. The 3.5 kB fragment corresponding to pBluescript along with the 5' 450 bases of the canola Fad2 cDNA was gel purified and ligated to the above described 812 base pair fragment. The ligation product was amplified by transformation of E. coli and plasmid DNA isolation. The EcoRI site remaining at the cloning junction between pBluescript and the canola Fad2 cDNA was destroyed by digestion, blunting and religation. The recovered plasmid was called pM2CFd2.

pM2CFd2 was digested with EcoRV and SmaI to remove the Fad2 insert as a blunt ended fragment. The fragment was gel purified and cloned into the SmaI site of pBC (Stratagene, La Jolla, CA). A plasmid with the NotI site introduced by PCR oriented away from the existing NotI site in pBC was identified by NotI digestion and gel fractionation of the digests. The resulting construct then had NotI sites at both ends of the canola Fad2 cDNA fragment and was called pM3CFd2.

Vectors for transformation of the antisense cytoplasmic delta-12 desaturase constructions under control of the ß-conglycinin, Kunitz trypsin inhibitor III, napin and phaseolin promoters into plants using Agrobacterium tumefaciens were produced by constructing a binary Ti plasmid vector system (Bevan, (1984) Nucl.

Acids Res. 12:8711-8720). One starting vector for the system, (pZS199) is based on a vector which contains: (1) the chimeric gene nopaline synthase/neomycin phosphotransferase as a selectable marker for transformed plant cells (Brevan et al. (1984) Nature 304: 184-186), (2) the left and right borders of the T-DNA of the Ti plasmid (Brevan et al. (1984) Nucl. Acids Res. 12:8711-8720), (3) the E. coli lacZ a-complementing segment (Vieria and Messing (1982) Gene 19:259-267) with unique restriction endonuclease sites for Eco RI, Kpn I, Bam HI, and Sal I, (4) the bacterial replication origin from the Pseudomonas plasmid pVS1 (Itoh et al. (1984) Plasmid 11:206-220), and (5) the bacterial neomycin phosphotransferase gene from Tn5 (Berg et al. (1975) Proc. Natnl. Acad. Sci. U.S.A. 72:3628-3632) as a selectable marker for transformed A. tumefaciens. The nopaline synthase promoter in the plant selectable marker was replaced by the 35S promoter (Odell et al. (1985) Nature, 313:810-813) by a standard restriction endonuclease digestion and ligation strategy. The 35S promoter is required for efficient Brassica napus transformation as described below. A second vector (pZS212) was constructed by reversing the order of restriction sites in the unique site cloning region of pZS199

Canola napin promoter expression cassettes were consturcted as follows: Ten oligonucleotide primers were synthesized based upon the nucleotide sequence of napin lambda clone CGN1-2 published in European Patent Application EP 255378). The oligonucleotide sequences were:

- BR42 and BR43 corresponding to bases 1132 to 1156 (BR42) and the complement of bases 2248 to 2271 (BR43) of the sequence listed in Figure 2 of EP 255378.

- BR45 and BR46 corresponding to bases 1150 to 1170 (BR46) and the complement of bases 2120 to 2155 (BR45) of the sequence listed in Figure 2 of EP 255378. In addition BR46 had bases corresponding to a Sal I site (5'-GTCGAC-3') and a few additional bases (5'-TCAGGCCT-3') at its 5' end and BR45 had bases corresponding to a Bgl II site (5'-AGATCT-3') and two (5'-CT-3') additional bases at the 5' end of the primer,
- BR47 and BR48 corresponding to bases 2705 to 2723 (BR47) and bases 2643 to 2666 (BR48) of the sequence listed in Figure 2 of EP 255378. In addition BR47 had two (5'-CT-3') additional bases at the 5' end of the primer followed by bases corresponding to a Bgl II site (5'-AGATCT-3') followed by a few additional bases (5'-TCAGGCCT-3'),
- BR49 and BR50 corresponding to the complement of bases 3877 to 3897 (BR49) and the complement of bases 3985 to 3919 (BR50) of the sequence listed in Figure 2 of EP 255378. In addition BR49 had bases corresponding to a Sal I site (5'-GTCGAC-3') and a few additional bases (5'-TCAGGCCT-3') at its 5' end,
- BR57 and BR58 corresponding to the complement of bases 3875 to 3888 (BR57) and bases 2700 to 2714 (BR58) of the sequence listed in Figure 2 of EP 255378. In addition the 5' end of BR57 had some extra bases (5'-CCATGG-3') followed by bases corresponding to a Sac I site (5'-GAGCTC-3') followed by more additional bases (5'-GTCGACGAGG-3'). The 5' end of BR58 had additional bases (5'-GAGCTC-3') followed by bases corresponding to a Nco I site (5'-CCATGG-3') followed by additional bases (5'-AGATCTGGTACC-3').
- BR61 and BR62 corresponding to bases 1846 to 1865 (BR61) and bases 2094 to 2114 (BR62) of the sequence listed in Figure 2 of EP 255378. In addition the 5'

end of BR 62 had additional bases (5'-GACA-3') followed by bases corresponding to a Bgl II site (5'-AGATCT-3') followed by a few additional bases (5'-GCGGCCGC-3').

Genomic DNA from the canola variety 'Hyola401' (Zeneca Seeds) was used as a template for PCR amplification of the napin promoter and napin terminator regions. The promoter was first amplified using primers BR42 and BR43, and reamplified using primers BR45 and BR46. Plasmid pIMC01 was derived by digestion of the 1.0 kb promoter PCR product with SalI/BglII and ligation into SalI/BamHI digested pBluescript SK^+ (Stratagene). The napin terminator region was amplified using primers BR48 and BR50, and reamplified using primers BR47 and BR49. Plasmid pIMC06 was derived by digestion of the 1.2 kb terminator PCR product with SalI/BglII and ligation into SalI/BglII digested pSP72 (Promega). Using pIMC06 as a template, the terminator region was reamplified by PCR using primer BR57 and primer BR58. Plasmid pIMC101 containing both the napin promoter and terminator was generated by digestion of the PCR product with SacI/NcoI and ligation into SacI/NcoI digested pIMC01. Plasmid pIMC101 contains a 2.2 kb napin expression cassette including complete napin 5' and 3' non-translated sequences and an introduced NcoI site at the translation start ATG. Primer BR61 and primer BR62 were used to PCR amplify an ~270 bp fragment from the 3' end of the napin promoter. Plasmid pIMC401 was obtained by digestion of the resultant PCR product with EcoRI/BglII and ligation into EcoRI/BglII digested pIMC101. Plasmid pIMC401 contains a 2.2 kb napin expression cassette lacking the napin 5' non-translated sequence and includes a NotI site at the transcription start.

To construct the antisense expression vector, pM3CFd2 was digested with NotI as was pIMC401. The delta-12 desaturase containing insert from the digest of pM3CFd2 was gel isolated and ligated into the NotI digested and phosphatase treated pIMC401. An isolate in which the delta-12 desaturase was oriented antisense to the napin promoter was selected by digestion with XhoI and PflMI to give plasmid pNCFd2R. pNCFd2R was digested with SalI, phosphatase treated and ligated into pZS212 which had been opened by the same treatment. A plasmid with desired orientation of the introduced napin:delta-12 desaturase antisense transcription unit relative to the selectable marker was chosen by digestion with PvuI and the resulting binary vector was given the name pZNCFd2R.

Plasmid pML70 (described in Example 6 above) was digested with NcoI, blunted then digested with KpnI. Plasmid pM2CFd was digested with KpnI and SmaI and the isolated fragment ligated into the opened pML70 to give the antisense expression cassette pMKCFd2R. The promotor:delta-12 desaturase:terminator sequence was removed from pMKCFd2R by BamHI digestion and ligated into pZS199 which had been BamHI digested and phosphatase treated. The desired orientation relative to the selectable marker was determined by digestion with XhoI and PflMI to give the expression vector pZKCFd2R.

The expression vector containing the ß-conglicinin promoter was constructed by SmaI and EcoRV digestion of pM2CFd2 and ligation into SmaI cut pML109A. An isolate with the antisense orientation was identified by digestion with XhoI and PflmI, and the transcription unit was isolated by SalI and EcoRI digestion. The isolated SalI-EcoRI fragment was ligated into EcoRI-SalI digested pZS199 to give pCCFd2R.

The expression vector containing the phaseolin promoter was obtained using the same proceedure with pCW108 as the starting, promoter containing vector and pZS212 as the binary portion of the vector to give pZPhCFd2R.

Agrobacterium-Mediated Transformation Of Brassica Napus

The binary vectors pZNCFd2R, pZCCFd2R, pZPhCFd2R, and pZNCFd2R were transferred by a freeze/thaw method (Holsters et al. (1978) Mol Gen Genet 163:181-187) to the *Agrobacterium* strain LBA4404/pAL4404 (Hockema et al. (1983), Nature 303:179-180).

Brassica napus cultivar "Westar" was transformed by co-cultivation of seedling pieces with disarmed *Agrobacterium tumefaciens* strain LBA4404 carrying the the appropriate binary vector.

B. napus seeds were sterilized by stirring in 10% Chlorox, 0.1% SDS for thirty min, and then rinsed thoroughly with sterile distilled water. The seeds were germinated on sterile medium containing 30 mM $CaCl_2$ and 1.5% agar, and grown for six days in the dark at 24°C.

Liquid cultures of *Agrobacterium* for plant transformation were grown overnight at 28°C in Minimal A medium containing 100 mg/L kanamycin. The bacterial cells were pelleted by centrifugation and resuspended at a concentration of 10^8 cells/mL in liquid Murashige and Skoog Minimal Organic medium containing 100 µM acetosyringone.

B. napus seedling hypocotyls were cut into 5 mm segments which were immediately placed into the bacterial suspension. After 30 min, the hypocotyl pieces were removed from the bacterial suspension and placed onto BC-35 callus medium containing 100 µM acetosyringone. The plant tissue and *Agrobacteria* were co-cultivated for three days at 24°C in dim light.

The co-cultivation was terminated by transferring the hypocotyl pieces to BC-35 callus medium containing 200 mg/L carbenicillin to kill the Agrobacteria, and 25 mg/L kanamycin to select for transformed plant cell growth. The seedling pieces were incubated on this medium for three weeks at 28°C under continuous light.

After four weeks, the segments were transferred to BS-48 regeneration medium containing 200 mg/L carbenicillin and 25 mg/L kanamycin. Plant tissue was subcultured every two weeks onto fresh selective regeneration medium, under the same culture conditions described for the callus medium. Putatively transformed calli grew rapidly on regeneration medium; as calli reached a diameter of about 2 mm, they were removed from the hypocotyl pieces and placed on the same medium lacking kanamycin.

Shoots began to appear within several weeks after transfer to BS-48 regeneration medium. As soon as the shoots formed discernable stems, they were excised from the calli, transferred to MSV-1A elongation medium, and moved to a 16:8 h photoperiod at 24°C.

Once shoots had elongated several internodes, they were cut above the agar surface and the cut ends were dipped in Rootone. Treated shoots were planted directly into wet Metro-Mix 350 soiless potting medium. The pots were covered with plastic bags which were removed when the plants were clearly growing -- after about ten days.

Plants were grown under a 16:8 h photoperiod, with a daytime temperature of 23°C and a nighttime temperature of 17°C. When the primary flowering stem began to elongate, it was covered with a mesh pollen-containment bag to prevent outcrossing. Self-pollination was facilitated by shaking the plants several times each day. Fifty-one plants have thus far been obtained from transformations using both pZCCFd2R and pZPhCFd2R, 40

plants have been obtained from pZKCFd2R and 26 from pZNCFd2R.

Minimal A Bacterial Growth Medium

Dissolve in distilled water:

10.5 grams potassium phosphate, dibasic

4.5 grams potassium phosphate, monobasic

1.0 gram ammonium sulfate

0.5 gram sodium citrate, dihydrate

Make up to 979 mL with distilled water

Autoclave

Add 20 mL filter-sterilized 10% sucrose

Add 1 mL filter-sterilized 1 M $MgSO_4$

Brassica Callus Medium BC-35

Per liter:

Murashige and Skoog Minimal Organic Medium (MS salts, 100 mg/L i-inositol, 0.4 mg/L thiamine; GIBCO #510-3118)

30 grams sucrose

18 grams mannitol

0.5 mg/L 2,4-D

0.3 mg/L kinetin

0.6% agarose

pH 5.8

Brassica Regeneration Medium BS-48

Murashige and Skoog Minimal Organic Medium

Gamborg B5 Vitamins (SIGMA #1019)

10 grams glucose

250 mg xylose

600 mg MES

0.4% agarose

pH 5.7

Filter-sterilize and add after autoclaving:

2.0 mg/L zeatin

0.1 mg/L IAA

Brassica Shoot Elongation Medium MSV-1A

Murashige and Skoog Minimal Organic Medium
Gamborg B5 Vitamins
10 grams sucrose
0.6% agarose
pH 5.8

Analysis Of Transgenic Brassica Napus Seeds Containing An Antisense Microsomal Delta-12 Desaturase Construct

Fifty-one plants were obtained from transformation with both pZPhCFd2R and pZCCFd2R, 40 were obtained from pZKCFd2R, and 26 from pZNCFd2R. The relative levels of oleate (18:1), linoleate (18:2) and linolinate (18:3) change during development so that reliable determination of seed fatty acid phenotype is best obtained from seed which has undergone nomal maturation and drydown. Relatively few transformed plants have gone through to maturity, however seeds were sampled from plants which had been transferred to pots for at least 80 days and which had pods that had yellowed and contained seeds with seed coats which had black pigmentation. Plants were chosen for early anlaysis based on promotor type, presence and copy number of the inserted delta-12 desaturase antisense gene and fertility of the plant.

Fatty acid analysis was done on either individual seeds from transformed and control plants, or on 40 mg of bulk seed from individual plants as described in Example 6. Southern analysis for detection of the presence of canola delta-12 desaturase antisense genes was done on DNA obtained from leaves of transformed plants. DNA was digested either to release the promotor:delta-12 desaturase fragment from the transformation vector or to cut outside the coding region of the delta-12 desaturase antisense gene, but within the left and right T-DNA borders of the vector.

TABLE 14

Relative Fatty Acid Profiles of Microsomal Delta-12 Desaturase Antisense Transformed and Control Brassica Napus Seeds

				% of TOTAL FATTY ACIDS				
PLANT #	PROMOTER	COPY#	AGE*	16:0	18:0	18:1	18:2	18:3

153-83	conglycinin	2	106	4.1	1.6	68.5	16.7	6.3

*Seed sampeling date in days after the plant was tranferred to soil

The expected fatty acid phenotype for antisense suppression of the delta-12 desaturase is decreased relative content of 18:2 with a corresponding increase in 18:1. Plant numbers 151-22 and 158-8 both show a substantial decrease in 18:2 content of bulk seed when compared to the westar control at 83 days after planting. Plant 151-22 also shows this difference at maturity in comparison to either the westar control or plant 151-127, which was transformed with the selectable marker gene but not the delta-12 desaturase antisense gene.

Since the fatty acid analysis was done on seeds from the primary transformant, individual seed should be segregating for the presense of the transgene copy or copies. The segregating phenotypes serve as an internal control for the effect of the delta-12 desaturase antisense gene. The relative fatty acid phenotypes for 10 individual westar seeds, 10 individual 151-22 seeds and 12 individual 158-8 seeds are given in Table 15 below.

3.48	1.38	83.15	4.91	4.53
3.55	1.92	83.69	4.20	3.70

The westar control shows comparatively little seed to seed variation in content of 18:1 or 18:2. Further the ratio of 18:3/18:2 remains very constant between seeds at about 0.35. Plant #158-8 should show a segregation ratio of either 1:2:1 or 1:3 since by Southern analysis it contains a single transgene. The 1:2:1 ratio would indicate a semi-dominant, copy number effect while the 1:3 ratio would indicate complete dominance. Two wild type 158-8 segregants are clear in Table 15, while the remaing seeds may either be the same, or the two seeds at greater than 84% 18:1 may represent the homozygous transgeneic. In either case the fatty acid phenotypes of the seeds are as expected for effective delta-12 desaturase suppression in this generation. The fatty acid phenotypes of the seeds of plant 151-22 show variation in their 18:1 and 18:2 content, with 18:1 higher than the control average and 18:2 lower. The segregation is apparently quite complex, as would be expected of a multi-copy transgenic plant.

CLAIMS

1. An isolated nucleic acid fragment comprising a nucleic acid sequence encoding a fatty acid desaturase or a fatty acid desaturase-related enzyme with an amino acid identity of 50% or greater to the polypeptide encoded by SEQ ID NOS:1, 3, 5, 7, 9, 11, or 15.

2. The isolated nucleic acid fragment of Claim 1 wherein the amino acid identity is 60% or greater to the polypeptide encoded by SEQ ID NOS:1, 3, 5, 7, 9, 11, or 15.

3. The isolated nucleic acid fragment of Claim 1 wherein the nucleic acid identity is 90% or greater to SEQ ID NOS:1, 3, 5, 7, 9, 11, or 15.

4. The isolated nucleic acid fragment of Claim 1 wherein said fragment is isolated from an oil-producing plant species.

5. An isolated nucleic acid fragment comprising a nucleic acid sequence encoding a delta-12 fatty acid hydroxylase.

6. A chimeric gene capable of causing altered levels of ricinoleic acid in a transformed plant cell, said chimeric gene comprising a nucleic acid fragment of Claim 5, said fragment operably linked to suitable regulatory sequences.

7. A chimeric gene capable of causing altered levels of fatty acids in a transformed plant cell, said chimeric gene comprising a nucleic acid fragment of any of Claims 1, 2, 3, said fragment operably linked to suitable regulatory sequences.

8. Plants containing a chimeric gene of Claim 6 or Claim 7.

9. Oil obtained from seeds of the plants containing the chimeric genes of Claim 8.

10. A method of producing seed oil containing altered levels of unsaturated fatty acids comprising:

(a) transforming a plant cell of an oil-producing species with a chimeric gene of Claim 5;

(b) growing fertile plants from the transformed plant cells of step (a);

(c) screening progeny seeds from the fertile plants of step (b) for the desired levels of unsaturated fatty acids; and

(d) processing the progeny seed of step (c) to obtain seed oil containing altered levels of unsaturated fatty acids.

11. A method of molecular breeding to obtain altered levels of a fatty acid in seed oil of oil-producing plant species comprising:

(a) making a cross between two varieites of oil-producing species differing in the fatty acid trait;

(b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and

(c) hybridizing the Southern blot with the radiolabelled nucleic acid fragment of Claim 1.

12. A method of RFLP mapping comprising:

(a) making a cross between two varieties of plants;

(b) making a Southern blot of restriction enzyme digested genomic DNA isolated from several progeny plants resulting from the cross of step (a); and

(c) hybridizing the Southern blot with the radiolabelled nucleic acid fragments of Claim 1.

13. A method to isolate nucleic acid fragments encoding fatty acid desaturases and related enzymes, comprising:

(a) comparing SEQ ID NOS:2, 4, 6, 8, 10, or 12 and other fatty acid desaturase polypeptide sequences;

(b) identifying the conserved sequences of 4 or more amino acids obtained in step a;

(c) desiging degenerate oligomers based on the conserved sequences identified in step b; and

(d) using the degenerate oligomers of step c to isolate sequences encoding fatty acid desaturases and desaturase-related enzymes by sequence dependent protocols.

14. An isolated nucleic acid fragment of Claim 1 comprising a nucleic acid sequence encoding a plant microsomal delta-12 fatty acid desaturase.

INTERNATI NAL SEARCH REPORT

Intern al Application No
PCT/US 93/09987

A. CLASSIFICATION OF SUBJECT MATTER
IPC 5 C12N15/53 C12N15/82 C11B1/00 C12Q1/68 A01H5/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 5 C12N C11B A01H

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	JOURNAL OF BIOLOGICAL CHEMISTRY vol. 267, no. 3, 25 January 1992, BALTIMORE, MD US pages 1502 - 1509 MIQUEL, M., ET AL. 'Arabidopsis mutants deficient in polyunsaturated fatty acid synthesis' cited in the application	9
A	see the whole document	1-4

X	THEOR. APPL. GENET. vol. 80, 1990 pages 234 - 240 LEMIEUX, B., ET AL. 'Mutants of Arabidopsis with alterations in seed lipid composition' see the whole document	9

	-/--	

[X] Further documents are listed in the continuation of box C.

[X] Patent family members are listed in annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

(54) Title: PRODUCTION OF HYDROXYLATED FATTY ACIDS IN GENETICALLY MODIFIED PLANTS

(57) Abstract

This invention relates to plant fatty acid hydroxylases. Methods to use conserved amino acid or nucleotide sequences to obtain plant fatty acid hydroxylases are described. Also described is the use of cDNA clones encoding a plant hydroxylase to produce a family of hydroxylated fatty acids in transgenic plants. In addition, the use of genes encoding fatty acid hydroxylases or desaturases to alter the level of lipid fatty acid unsaturation in transgenic plants is described.

PRODUCTION OF HYDROXYLATED FATTY ACIDS IN GENETICALLY MODIFIED PLANTS

TECHNICAL FIELD

The present invention concerns the identification of nucleic acid sequences and constructs, and methods related thereto, and the use of these sequences and constructs to produce genetically modified plants for the purpose of altering the fatty acid composition of plant oils, waxes and related compounds.

DEFINITIONS

The subject of this invention is a class of enzymes that introduce a hydroxyl group into several different fatty acids resulting in the production of several different kinds of hydroxylated fatty acids. In particular, these enzymes catalyze hydroxylation of oleic acid to 12-hydroxy oleic acid and icosenoic acid to 14-hydroxy icosenoic acid. Other fatty acids such as palmitoleic and erucic acids may also be substrates. Since it is not possible to refer to the enzyme by reference to a unique substrate or product, the enzyme is referred throughout as kappa hydroxylase to indicate that the enzyme introduces the hydroxyl three carbons distal (i.e., away from the carboxyl carbon of the acyl chain) from a double bond located near the center of the acyl chain.

The following fatty acids are also the subject of this invention: ricinoleic acid, 12-hydroxyoctadec-*cis*-9-enoic acid ($12OH\text{-}18{:}1^{cis\Delta9}$); lesquerolic acid, 14-hydroxy-*cis*-11-icosenoic acid ($14OH\text{-}20{:}1^{cis\Delta11}$); densipolic acid, 12-hydroxyoctadec-*cis*-9,15-dienoic acid ($12OH\text{-}18{:}2^{cis\Delta9,15}$); auricolic acid, 14-hydroxy-*cis*-11,17-icosadienoic acid (14OH-

$20{:}2^{cis\Delta 11,17}$); hydroxyerucic, 16-hydroxydocos-*cis*-13-enoic acid ($16OH\text{-}22{:}1^{cis\Delta 13}$); hydroxypalmitoleic, 12-hydroxyhexadec-*cis*-9-enoic ($12OH\text{-}16{:}1^{cis\Delta 9}$); icosenoic acid ($20{:}1^{cis\Delta 11}$). It will be noted that icosenoic acid is spelled eicosenoic acid in some countries.

BACKGROUND

Extensive surveys of the fatty acid composition of seed oils from different species of higher plants have resulted in the identification of at least 33 structurally distinct monohydroxylated plant fatty acids, and 12 different polyhydroxylated fatty acids that are accumulated by one or more plant species (reviewed by van de Loo et al., 1993). Ricinoleic acid, the principal constituent of the seed oil from the castor plant *Ricinus communis* (L.), is of commercial importance. The present inventors have cloned a gene from this species that encodes a fatty acid hydroxylase, and have used this gene to produce ricinoleic acid in transgenic plants of other species. Some of this scientific evidence has been published by the present inventors (van de Loo et al., 1995).

The use of the castor hydroxylase gene to also produce other hydroxylated fatty acids such as lesquerolic acid, densipolic acid, hydroxypalmitoleic, hydroxyerucic and auricolic acid in transgenic plants is the subject of this invention. In addition, the identification of a gene encoding a homologous hydroxylase from *Lesquerella fendleri*, and the use of this gene to produce these hydroxylated fatty acids in transgenic plants is the subject of this invention.

Castor is a minor oilseed crop. Approximately 50% of the seed weight is oil (triacylglycerol) in which 85-90% of total fatty acids are the hydroxylated fatty acid, ricinoleic acid. Oil pressed or extracted from castor seeds has many industrial uses based upon the properties endowed by the hydroxylated fatty acid. The most important uses are production of paints and varnishes, nylon-type synthetic polymers, resins, lubricants, and cosmetics (Atsmon, 1989).

In addition to oil, the castor seed contains the extremely toxic protein ricin, allergenic proteins, and the alkaloid ricinine. These constituents preclude the use of the untreated seed meal (following oil extraction) as a livestock feed, normally an important economic aspect of oilseed utilization. Furthermore, with the variable nature of castor plants and a lack of investment in breeding, castor has few favorable agronomic characteristics.

For a combination of these reasons, castor is no longer grown in the United States and the development of an alternative domestic source of hydroxylated fatty acids would be attractive. The production of ricinoleic acid, the important constituent of castor oil, in an established oilseed crop through genetic engineering would be a particularly effective means of creating a domestic source.

Because there is no practical source of lesquerolic, densipolic and auricolic acids from plants that are adapted to modern agricultural practices, there is currently no large-scale use of these fatty acids by industry. However, the fatty

acids would have uses similar to those of ricinoleic acid if they could be produced in large quantities at comparable cost to other plant-derived fatty acids (Smith, 1985).

Plant species, such as certain species in the genus *Lesquerella*, that accumulate a high proportion of these fatty acids, have not been domesticated and are not currently considered a practical source of fatty acids (Hirsinger, 1989). This invention represents a useful step toward the eventual production of these and other hydroxylated fatty acids in transgenic plants of agricultural importance.

The taxonomic relationships between plants having similar or identical kinds of unusual fatty acids have been examined (van de Loo et al., 1993). In some cases, particular fatty acids occur mostly or solely in related taxa. In other cases there does not appear to be a direct link between taxonomic relationships and the occurrence of unusual fatty acids. In this respect, ricinoleic acid has now been identified in 12 genera from 10 families (reviewed in van de Loo et al., 1993). Thus, it appears that the ability to synthesize hydroxylated fatty acids has evolved several times independently during the radiation of the angiosperms. This suggested to us that the enzymes which introduce hydroxyl groups into fatty acids arose by minor modifications of a related enzyme.

Indeed, as shown herein, the sequence similarity between Δ12 fatty acid desaturases and the kappa hydroxylase from castor is so high that it is not possible to unambiguously determine whether a particular enzyme is a d saturase or a hydroxylase

on the basis of evidence in the scientific literature. Similarly, a patent application (PCT WO 94/11516) that purports to teach the isolation and use of Δ12 fatty acid desaturases does not teach how to distinguish a hydroxylase from a desaturase. In view of the importance of being able to distinguish between these activities for the purpose of genetic engineering of plant oils, the utility of that application is limited to the several instances where direct experimental evidence (e.g., altered fatty acid composition in transgenic plants) was presented to support the assignment of function. A method for distinguishing between fatty acid desaturases and fatty acid hydroxylases on the basis of amino acid sequence of the enzyme is also a subject of this invention.

A feature of hydroxylated or other unusual fatty acids is that they are generally confined to seed triacylglycerols, being largely excluded from the polar lipids by unknown mechanisms (Battey and Ohlrogge 1989; Prasad et al., 1987). This is particularly intriguing since diacylglycerol is a precursor of both triacylglycerol and polar lipid. With castor microsomes, there is some evidence that the pool of ricinoleoyl-containing polar lipid is minimized by a preference of diacylglycerol acyltransferase for ricinoleate-containing diacylglycerols (Bafor et al., 1991). Analyses of vegetative tissues have generated few reports of unusual fatty acids, other than those occurring in the cuticle. The cuticle contains various hydroxylated fatty acids which are interesterified to produce a high molecular weight polyester which serves a structural role. A small number of other

exceptions exist in which unusual fatty acids are found in tissues other than the seed.

The biosynthesis of ricinoleic acid from oleic acid in the developing endosperm of castor (*Ricinus communis*) has been studied by a variety of methods. Morris (1967) established in double-labeling studies that hydroxylation occurs directly by hydroxyl substitution rather than via an unsaturated-, keto- or epoxy-intermediate. Hydroxylation using oleoyl-CoA as precursor can be demonstrated in crude preparations or microsomes, but activity in microsomes is unstable and variable, and isolation of the microsomes involved a considerable, or sometimes complete loss of activity (Galliard and Stumpf, 1966; Moreau and Stumpf, 1981). Oleic acid can replace oleoyl-CoA as a precursor, but only in the presence of CoA, Mg^{2+} and ATP (Galliard and Stumpf, 1966) indicating that activation to the acyl-CoA is necessary. However, no radioactivity could be detected in ricinoleoyl-CoA (Moreau and Stumpf, 1981). These and more recent observations (Bafor et al., 1991) have been interpreted as evidence that the substrate for the castor oleate hydroxylase is oleic acid esterified to phosphatidylcholine or another phospholipid.

The hydroxylase is sensitive to cyanide and azide, and dialysis against metal chelators reduces activity, which could be restored by addition of $FeSO_4$, suggesting iron involvement in enzyme activity (Galliard and Stumpf, 1966). Ricinoleic acid synthesis requires molecular oxygen (Galliard and Stumpf, 1966; Moreau and Stumpf 1981) and requires NAD(P)H to reduce cytochrome b5 which is thought to be the intermediate electron donor for the

hydroxylase reaction (Smith et al., 1992). Carbon monoxide does not inhibit hydroxylation, indicating that a cytochrome P450 is not involved (Galliard and Stumpf, 1966; Moreau and Stumpf 1981). Data from a study of the substrate specificity of the hydroxylase show that all substrate parameters (i.e., chain length and double bond position with respect to both ends) are important; deviations in these parameters caused reduced activity relative to oleic acid (Howling et al., 1972). The position at which the hydroxyl was introduced, however, was determined by the position of the double bond, always being three carbons distal. Thus, the castor acyl hydroxylase enzyme can produce a family of different hydroxylated fatty acids depending on the availability of substrates. Thus, as a matter of convenience, the enzyme is referred throughout this specification as a kappa hydroxylase (rather than an oleate hydroxylase) to indicate the broad substrate specificity.

The castor kappa hydroxylase has many superficial similarities to the microsomal fatty acyl desaturases (Browse and Somerville, 1991). In particular, plants have a microsomal oleate desaturase active at the Δ12 position. The substrate of this enzyme (Schmidt et al., 1993) and of the hydroxylase (Bafor et al., 1991) appears to be a fatty acid esterified to the *sn-2* position of phosphatidylcholine. When oleate is the substrate, the modification occurs at the same position (Δ12) in the carbon chain, and requires the same cofactors, namely electrons from NADH via cytochrome b_5 and molecular oxygen. Neither enzyme is inhibited

by carbon monoxide (Moreau and Stumpf, 1981), the characteristic inhibitor of cytochrome P450 enzymes.

There do not appear to have been any published biochemical studies of the properties of the hydroxylase enzyme(s) in *Lesquerella*.

Conceptual basis of the invention

The present inventors have described the use of a cDNA clone from castor for the production of ricinoleic acid in transgenic plants. As noted above, biochemical studies had suggested that the castor hydroxylase may not have strict specificity for oleic acid but would also catalyze hydroxylation of other fatty acids such as icosenoic acid ($20{:}1^{cis\Delta 11}$) (Howling et al., 1972). Based on these studies, expression of kappa hydroxylase in transgenic plants of species such as *Brassica napus* and *Arabidopsis thaliana* that accumulate fatty acids such as icosenoic acid ($20{:}1^{cis\Delta 11}$) and erucic acid (13-docosenoic acid; $22{:}1^{cis\Delta 13}$) may cause the accumulation of hydroxylated derivatives of these fatty acids due to the activity of the hydroxylase on these fatty acids. Direct evidence is presented in Example 1 that hydroxlyated derivatives of ricinoleic, lesquerolic, densipolic and auricolic fatty acids are produced in transgenic *Arabidopsis* plants.

Example 2 shows the isolation of a novel kappa hydroxylase gene from *Lesquerella fendleri*.

In view of the high degree of sequence similarity between Δ12 fatty acid desaturases and the castor hydroxylase (van de Loo et al., 1995), the validity of claims (e.g., PCT WO 94/11516) for using a limited set of desaturase or hydroxylase

genes or sequences derived therefrom to identify genes of identical function from other species must be viewed with skepticism. In this application, the present inventors teach a method by which hydroxylase genes can be distinguished from desaturases. The present inventors describe a mechanistic basis for the similar reaction mechanisms of desaturases and hydroxylases. Briefly, the available evidence suggests that fatty acid desaturases have a similar reaction mechanism to the bacterial enzyme methane monooxygenase which catalyses a reaction involving oxygen-atom transfer ($CH_4 \rightarrow CH_3OH$) (van de Loo et al., 1993). The cofactor in the hydroxylase component of methane monooxygenase is termed a μ-oxo bridged diiron cluster (FeOFe). The two iron atoms of the FeOFe cluster are liganded by protein-derived nitrogen or oxygen atoms, and are tightly redox-coupled by the covalently-bridging oxygen atom. The FeOFe cluster accepts two electrons, reducing it to the diferrous state, before oxygen binding. Upon oxygen binding, it is likely that heterolytic cleavage also occurs, leading to a high valent oxoiron reactive species that is stabilized by resonance rearrangements possible within the tightly coupled FeOFe cluster. The stabilized high-valent oxoiron state of methane monooxygenase is capable of proton extraction from methane, followed by oxygen transfer, giving methanol. The FeOFe cofactor has been shown to be directly relevant to plant fatty acid modifications by the demonstration that castor stearoyl-ACP desaturase contains this type of cofactor (Fox et al., 1993).

On the basis of the foregoing considerations, the present inventors suggest that the castor oleate hydroxylase might be a structurally modified fatty acyl desaturase, based upon three arguments. The first argument involves the taxonomic distribution of plants containing ricinoleic acid. Ricinoleic acid has been found in 12 genera of 10 families of higher plants (reviewed in van de Loo et al., 1993). Thus, plants in which ricinoleic acid occurs are found throughout the plant kingdom, yet close relatives of these plants do not contain the unusual fatty acid. This pattern suggests that the ability to synthesize ricinoleic acid has arisen (and been lost) several times independently, and is therefore has recently diverged. In other words, the ability to synthesize ricinoleic acid has evolved rapidly, suggesting that a relatively minor genetic change in the structure of the ancestral enzyme was necessary to accomplish it.

The second argument is that many biochemical properties of castor kappa hydroxylase are similar to those of the microsomal desaturases, as discussed above (e.g., both preferentially act on fatty acids esterified to the sn-2 position of phosphatidylcholine, both use cytochrome b5 as an intermediate electron donor, both are inhibited by cyanide, both require molecular oxygen as a substrate, both are thought to be located in the endoplasmic reticulum).

The third argument stems from the discussion of oxygenase cofactors above, in which it is suggested that the plant membrane bound fatty acid desaturases may have a μ-oxo bridged diiron cluster-type cofactor, and that such cofactors are capable

of catalyzing both fatty acid desaturations and hydroxylations, depending upon the electronic and structural properties of the protein active site.

Taking these three arguments together, the present inventors suggest that kappa hydroxylase of castor endosperm is homologous to the microsomal oleate Δ12 desaturase found in all plants. A number of genes encoding microsomal Δ12 desaturases from various species have recently been cloned (Okuley et al., 1994) and substantial information about the structure of these enzymes is now known (Shanklin et al., 1994). Hence, in the following invention, the present inventors teach how to use structural information to isolate and identify kappa hydroxylase genes. This example teaches the method by which any carbon-monoxide insensitive plant fatty acyl hydroxylase gene can be identified by one skilled in the art.

An unpredicted outcome of our studies on the castor hydroxylase gene in transgenic *Arabidopsis* plants was the discovery that expression of the hydroxylase leads to increased accumulation of oleic acid in seed lipids. Because of the low nucleotide sequence homology between the castor hydroxylase and the Δ12-desaturase (about 67%), it is unlikely that this effect is due to silencing (also called sense-suppression or cosuppression) of the expression of the desaturase gene by the hydroxylase gene. Whatever the basis for the effect, this invention teaches the use of hydroxylase genes to alter the level of fatty acid unsaturation in transgenic plants. This invention also teaches the use of genetically modified hydroxylase and desaturase

genes to achieve directed modification of fatty acid unsaturation levels.

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A-D show the mass spectra of hydroxy fatty acids standards (Figure 1A, O-TMS-methylricinoleate; Figure 1B, O-TMS-methyl densipoleate; Figure 1C, O-TMS-methyl-lesqueroleate; and Figure 1D, O-TMS-methylauricoleate).

SUMMARY OF THE INVENTION

This invention relates to plant fatty acyl hydroxylases. Methods to use conserved amino acid or nucleotide sequences to obtain plant fatty acyl hydroxylases are described. Also described is the use of cDNA clones encoding a plant hydroxylase to produce a family of hydroxylated fatty acids in transgenic plants.

In a first embodiment, this invention is directed to recombinant DNA constructs which can provide for the transcription, or transcription and translation (expression) of the plant kappa hydroxylase sequence. In particular, constructs which are capable of transcription, or transcription and translation in plant host cells are preferred. Such constructs may contain a variety of regulatory regions including transcriptional initiation regions obtained from genes preferentially expressed in plant seed tissue. In a second aspect, this invention relates to the presence of such constructs in host cells, especially plant host cells which have an expressed plant kappa hydroxylase therein.

In yet another aspect, this invention relates to a method for producing a plant kappa hydroxylase in a host cell or progeny thereof via the expression

of a construct in the cell. Cells containing a plant kappa hydroxylase as a result of the production of the plant kappa hydroxylase encoding sequence are also contemplated herein.

In another embodiment, this invention relates to methods of using a DNA sequence encoding a plant kappa hydroxylase for the modification of the proportion of hydroxylated fatty acids produced within a cell, especially plant cells. Plant cells having such a modified hydroxylated fatty acid composition are also contemplated herein.

In a further aspect of this invention, plant kappa hydroxylase proteins and sequences which are related thereto, including amino acid and nucleic acid sequences, are contemplated. Plant kappa hydroxylase exemplified herein includes a *Lesquerella fendleri* fatty acid hydroxylase. This exemplified fatty acid hydroxylase may be used to obtain other plant fatty acid hydroxylases of this invention.

In a further aspect of this invention, a nucleic acid sequence which directs the seed specific expression of an associated polypeptide coding sequence is described. The use of this nucleic acid sequence or fragments derived therefrom, to obtain seed-specific expression in higher plants of any coding sequence is contemplated herein.

In a further aspect of this invention, the use of genes encoding fatty acyl hydroxylases of this invention are used to alter the amount of fatty acid unsaturation of seed lipids. The present invention further discloses the use of genetically modified hydroxylase and desaturase genes to achieve

directed modification of fatty acid unsaturation levels.

DETAILED DESCRIPTION OF THE INVENTION

A genetically transformed plant of the present invention which accumulates hydroxylated fatty acids can be obtained by expressing the double-stranded DNA molecules described in this application.

A plant fatty acid hydroxylase of this invention includes any sequence of amino acids, such as a protein, polypeptide or peptide fragment, or nucleic acid sequences encoding such polypeptides, obtainable from a plant source which demonstrates the ability to catalyze the production of ricinoleic, lesquerolic, hydroxyerucic (16-hydroxydocos-*cis*-13-enoic acid) or hydroxypalmitoleic (12-hydroxyhexadec-*cis*-9-enoic) from CoA, ACP or lipid-linked monoenoic fatty acid substrates under plant enzyme reactive conditions. By "enzyme reactive conditions" is meant that any necessary conditions are available in an environment (i.e., such factors as temperature, pH, lack of inhibiting substances) which will permit the enzyme to function.

Preferential activity of a plant fatty acid hydroxylase toward a particular fatty acyl substrate is determined upon comparison of hydroxylated fatty acid product amounts obtained per different fatty acyl substrates. For example, by "oleate preferring" is meant that the hydroxylase activity of the enzyme preparation demonstrates a preference for oleate-containing substrates over other substrates. Although the precise substrate of the castor fatty

acid hydroxylase is not known, it is thought to be a monounsaturated fatty acid moiety which is esterified to a phospholipid such as phosphatidylcholine. However, it is also possible that monounsaturated fatty acids esterified to phosphatidylethanolamine, phosphatidic acid or a neutral lipid such as diacylglycerol or a Coenzyme-A thioester may also be substrates.

As noted above, significant activity has been observed in radioactive labelling studies using fatty acyl substrates other than oleate (Howling et al., 1972) indicating that the substrate specificity is for a family of related fatty acyl compounds. Because the castor hydroxylase introduces hydroxy groups three carbons from a double bond, proximal to the methyl carbon of the fatty acid, the enzyme is termed a kappa hydroxylase for convenience. Of particular interest, the present invention discloses that the castor kappa hydroxylase may be used for production of 12-hydroxy-9-octadecenoic acid (ricinoleate), 12-hydroxy-9-hexadecenoic acid, 14-hydroxy-11-eicosenoic acid, 16-hydroxy-13-docosenoic acid, 9-hydroxy-6-octadecenoic acid by expression in plants species which produce the non-hydroxylated precursors. The present invention also discloses production of additionally modified fatty acids such as 12-hydroxy-9,15-octadecadienoic acid that result from desaturation of hydroxylated fatty acids (e.g., 12-hydroxy-9-octadecenoic acid in this example).

The present invention also discloses that future advances in the genetic engineering of plants will lead to production of substrate fatty acids, such as icosenoic acid esters, and palmitoleic acid esters in plants that do not normally accumulate

such fatty acids. The invention described herein may be used in conjunction with such future improvements to produce hydroxylated fatty acids of this invention in any plant species that is amenable to directed genetic modification. Thus, the applicability of this invention is not limited in our conception only to those species that currently accumulate suitable substrates.

As noted above, a plant kappa hydroxylase of this invention will display activity towards various fatty acyl substrates. During biosynthesis of lipids in a plant cell, fatty acids are typically covalently bound to acyl carrier protein (ACP), coenzyme A (CoA) or various cellular lipids. Plant kappa hydroxylases which display preferential activity toward lipid-linked acyl substrate are especially preferred because they are likely to be closely associated with normal pathway of storage lipid synthesis in immature embryos. However, activity toward acyl-CoA substrates or other synthetic substrates, for example, is also contemplated herein.

Other plant kappa hydroxylases are obtainable from the specific exemplified sequences provided herein. Furthermore, it will be apparent that one can obtain natural and synthetic plant kappa hydroxylases including modified amino acid sequences and starting materials for synthetic-protein modeling from the exemplified plant kappa hydroxylase and from plant kappa hydroxylases which are obtained through the use of such exemplified sequences. Modified amino acid sequences include sequences which have been mutated, truncated, elongated or the like, whether such sequences were

partially or wholly synthesized. Sequences which are actually purified from plant preparations or are identical or encode identical proteins thereto, regardless of the method used to obtain the protein or sequence, are equally considered naturally derived.

Thus, one skilled in the art will readily recognize that antibody preparations, nucleic acid probes (DNA and RNA) or the like may be prepared and used to screen and recover "homologous" or "related" kappa hydroxylases from a variety of plant sources. Typically, nucleic acid probes are labeled to allow detection, preferably with radioactivity although enzymes or other methods may also be used. For immunological screening methods, antibody preparations either monoclonal or polyclonal are utilized. Polyclonal antibodies, although less specific, typically are more useful in gene isolation. For detection, the antibody is labeled using radioactivity or any one of a variety of second antibody/enzyme conjugate systems that are commercially available.

Homologous sequences are found when there is an identity of sequence and may be determined upon comparison of sequence information, nucleic acid or amino acid, or through hybridization reactions between a known kappa hydroxylase and a candidate source. Conservative changes, such as Glu/Asp, Val/Ile, Ser/Thr, Arg/Lys and Gln/Asn may also be considered in determining sequence homology. Typically, a lengthy nucleic acid sequence may show as little as 50-60% sequence identity, and more preferably at least about 70% sequence identity, between the target sequence and the given plant

kappa hydroxylase of interest excluding any deletions which may be present, and still be considered related. Amino acid sequences are considered homologous by as little as 25% sequence identity between the two complete mature proteins. (see generally, Doolittle, R.F., OF URFS and ORFS, University Science Books, CA, 1986.)

A genomic or other appropriate library prepared from the candidate plant source of interest may be probed with conserved sequences from the plant kappa hydroxylase to identify homologously related sequences. Use of an entire cDNA or other sequence may be employed if shorter probe sequences are not identified. Positive clones are then analyzed by restriction enzyme digestion and/or sequencing. When a genomic library is used, one or more sequences may be identified providing both the coding region, as well as the transcriptional regulatory elements of the kappa hydroxylase gene from such plant source. Probes can also be considerably shorter than the entire sequence. Oligonucleotides may be used, for example, but should be at least about 10, preferably at least about 15, more preferably at least 20 nucleotides in length. When shorter length regions are used for comparison, a higher degree of sequence identity is required than for longer sequences. Shorter probes are often particularly useful for polymerase chain reactions (PCR), especially when highly conserved sequences can be identified (see Gould et al., 1989 for examples of the use of PCR to isolate homologous genes from taxonomically diverse species).

When longer nucleic acid fragments are employed (>100 bp) as probes, especially when using

complete or large cDNA sequences, one would screen with low stringencies (for example, 40-50°C below the melting temperature of the probe) in order to obtain signal from the target sample with 20-50% deviation, i.e., homologous sequences (Beltz et al., 1983).

In a preferred embodiment, a plant kappa hydroxylase of this invention will have at least 60% overall amino acid sequence similarity with the exemplified plant kappa hydroxylase. In particular, kappa hydroxylases which are obtainable from an amino acid or nucleic acid sequence of a castor or *Lesquerella* kappa hydroxylase are especially preferred. The plant kappa hydroxylases may have preferential activity toward longer or shorter chain fatty acyl substrates. Plant fatty acyl hydroxylases having oleate-12-hydroxylase activity and eicosenoate-14-hydroxylase activity are both considered homologously related proteins because of *in vitro* evidence (Howling et al., 1972), and evidence disclosed herein, that the castor kappa hydroxylase will act on both substrates. Hydroxylated fatty acids may be subject to further enzymatic modification by other enzymes which are normally present or are introduced by genetic engineering methods. For example, 14-hydroxy-11,17-eicosadienoic acid, which is present in some *Lesquerella* species (Smith, 1985), is thought to be produced by desaturation of 14-hydroxy-11-eicosenoic acid.

Again, not only can gene clones and materials derived therefrom be used to identify homologous plant fatty acyl hydroxylases, but the resulting sequences obtained therefrom may also provide a

further method to obtain plant fatty acyl hydroxylases from other plant sources. In particular, PCR may be a useful technique to obtain related plant fatty acyl hydroxylases from sequence data provided herein. One skilled in the art will be able to design oligonucleotide probes based upon sequence comparisons or regions of typically highly conserved sequence. Of special interest are polymerase chain reaction primers based on the conserved regions of amino acid sequence between the castor kappa hydroxylase and the *L. fendleri* hydroxylase (SEQ ID NO:4). Details relating to the design and methods for a PCR reaction using these probes are described more fully in the examples.

It should also be noted that the fatty acyl hydroxylases of a variety of sources can be used to investigate fatty acid hydroxylation events in a wide variety of plant and *in vivo* applications. Because all plants synthesize fatty acids via a common metabolic pathway, the study and/or application of one plant fatty acid hydroxylase to a heterologous plant host may be readily achieved in a variety of species.

Once the nucleic acid sequence is obtained, the transcription, or transcription and translation (expression), of the plant fatty acyl hydroxylases in a host cell is desired to produce a ready source of the enzyme and/or modify the composition of fatty acids found therein in the form of free fatty acids, esters (particularly esterified to glycerolipids or as components of wax esters), estolides, or ethers. Other useful applications may be found when the host cell is a plant host cell, *in vitro* and *in vivo*. For example, by increasing the amount of an kappa

hydroxylase available to the plant, an increased percentage of ricinoleate or lesqueroleate (14-hydroxy-11-eicosenoic acid) may be provided.

Kappa Hydroxylase

By this invention, a mechanism for the biosynthesis of ricinoleic acid in plants is demonstrated. Namely, that a specific plant kappa hydroxylase having preferential activity toward fatty acyl substrates is involved in the accumulation of hydroxylated fatty acids in at least some plant species. The use of the terms ricinoleate or ricinoleic acid (or lesqueroleate or lesquerolic acid, densipoleate etc.) is intended to include the free acids, the ACP and CoA esters, the salts of these acids, the glycerolipid esters (particularly the triacylglycerol esters), the wax esters, the estolides and the ether derivatives of these acids.

The determination that plant fatty acyl hydroxylases are active in the *in vivo* production of hydroxylated fatty acids suggests several possibilities for plant enzyme sources. In fact, hydroxylated fatty acids are found in some natural plant species in abundance. For example, three hydroxy fatty acids related to ricinoleate occur in major amounts in seed oils from various *Lesquerella* species. Of particular interest, lesquerolic acid is a 20 carbon homolog of ricinoleate with two additional carbons at the carboxyl end of the chain (Smith, 1985). Other natural plant sources of hydroxylated fatty acids include but are not limited to seeds of the *Linum* genus, seeds of *Wrightia* species, *Lycopodium* species, *Strophanthus* species,

Convolvulaces species, *Calendula* species and many others (van de Loo et al., 1993).

Plants having significant presence of ricinoleate or lesqueroleate or desaturated other or modified derivatives of these fatty acids are preferred candidates to obtain naturally-derived kappa hydroxylases. For example, *Lesquerella densipila* contains a diunsaturated 18 carbon fatty acid with a hydroxyl group (van de Loo et al., 1993) that is thought to be produced by an enzyme that is closely related to the castor kappa hydroxylase, according to the theory on which this invention is based. In addition, a comparison between kappa hydroxylases and between plant fatty acyl hydroxylases which introduce hydroxyl groups at positions other than the 12-carbon of oleate or the 14-carbon of lesqueroleate or on substrates other than oleic acid and icosenoic acid may yield insights for gene identification, protein modeling or other modifications as discussed above.

Especially of interest are fatty acyl hydroxylases which demonstrate activity toward fatty acyl substrates other than oleate, or which introduce the hydroxyl group at a location other than the C12 carbon. As described above, other plant sources may also provide sources for these enzymes through the use of protein purification, nucleic acid probes, antibody preparations, protein modeling, or sequence comparisons, for example, and of special interest are the respective amino acid and nucleic acid sequences corresponding to such plant fatty acyl hydroxylases. Also, as previously described, once a nucleic acid sequence is obtained for the given plant hydroxylase, further plant

sequences may be compared and/or probed to obtain homologously related DNA sequences thereto and so on.

Genetic Engineering Applications

As is well known in the art, once a cDNA clone encoding a plant kappa hydroxylase is obtained, it may be used to obtain its corresponding genomic nucleic acid sequences thereto.

The nucleic acid sequences which encode plant kappa hydroxylases may be used in various constructs, for example, as probes to obtain further sequences from the same or other species. Alternatively, these sequences may be used in conjunction with appropriate regulatory sequences to increase levels of the respective hydroxylase of interest in a host cell for the production of hydroxylated fatty acids or study of the enzyme *in vitro* or *in vivo* or to decrease or increase levels of the respective hydroxylase of interest for some applications when the host cell is a plant entity, including plant cells, plant parts (including but not limited to seeds, cuttings or tissues) and plants.

A nucleic acid sequence encoding a plant kappa hydroxylase of this invention may include genomic, cDNA or mRNA sequence. By "encoding" is meant that the sequence corresponds to a particular amino acid sequence either in a sense or anti-sense orientation. By "recombinant" is meant that the sequence contains a genetically engineered modification through manipulation via mutagenesis, restriction enzymes, or the like. A cDNA sequence may or may not encode pre-processing sequences, such

as transit or signal peptide sequences. Transit or signal peptide sequences facilitate the delivery of the protein to a given organelle and are frequently cleaved from the polypeptide upon entry into the organelle, releasing the "mature" sequence. The use of the precursor DNA sequence is preferred in plant cell expression cassettes.

Furthermore, as discussed above the complete genomic sequence of the plant kappa hydroxylase may be obtained by the screening of a genomic library with a probe, such as a cDNA probe, and isolating those sequences which regulate expression in seed tissue.

Once the desired plant kappa hydroxylase nucleic acid sequence is obtained, it may be manipulated in a variety of ways. Where the sequence involves non-coding flanking regions, the flanking regions may be subjected to resection, mutagenesis, etc. Thus, transitions, transversions, deletions, and insertions may be performed on the naturally occurring sequence. In addition, all or part of the sequence may be synthesized. In the structural gene, one or more codons may be modified to provide for a modified amino acid sequence, or one or more codon mutations may be introduced to provide for a convenient restriction site or other purpose involved with construction or expression. The structural gene may be further modified by employing synthetic adapters, linkers to introduce one or more convenient restriction sites, or the like.

The nucleic acid or amino acid sequences encoding a plant kappa hydroxylase of this invention may be combined with other non-native, or "heterologous", sequences in a variety of ways. By

"heterologous" sequences is meant any sequence which is not naturally found joined to the plant kappa hydroxylase, including, for example, combination of nucleic acid sequences from the same plant which are not naturally found joined together.

The DNA sequence encoding a plant kappa hydroxylase of this invention may be employed in conjunction with all or part of the gene sequences normally associated with the kappa hydroxylase. In its component parts, a DNA sequence encoding kappa hydroxylase is combined in a DNA construct having, in the 5' to 3' direction of transcription, a transcription initiation control region capable of promoting transcription and/or translation in a host cell, the DNA sequence encoding plant kappa hydroxylase and a transcription and/or translation termination region.

Potential host cells include both prokaryotic and eukaryotic cells. A host cell may be unicellular or found in a multicellular differentiated or undifferentiated organism depending upon the intended use. Cells of this invention may be distinguished by having a plant kappa hydroxylase foreign to the wild-type cell present therein, for example, by having a recombinant nucleic acid construct encoding a plant kappa hydroxylase therein.

Depending upon the host, the regulatory regions will vary, including regions from viral, plasmid or chromosomal genes, or the like. For expression in prokaryotic or eukaryotic microorganisms, particularly unicellular hosts, a wide variety of constitutive or regulatable promoters may be employed. Expression in a

microorganism can provide a ready source of the plant enzyme. Among transcriptional initiation regions which have been described are regions from bacterial and yeast hosts, such as *E. coli*, *B. subtilis*, *Saccharomyces cerevisiae*, including genes such as beta-galactosidase, T7 polymerase, trpE or the like.

For the most part, the constructs will involve regulatory regions functional in plants which provide for modified production of plant kappa hydroxylase with resulting modification of the fatty acid composition. The open reading frame, coding for the plant kappa hydroxylase or functional fragment thereof will be joined at its 5' end to a transcription initiation regulatory region. Numerous transcription initiation regions are available which provide for a wide variety of constitutive or regulatable, e.g., inducible, transcription of the structural gene functions.

Among transcriptional initiation regions used for plants are such regions associated with the structural genes such as for nopaline and mannopine synthases, or with napin, soybean β-conglycinin, oleosin, 12S storage protein, the cauliflower mosaic virus 35S promoters or the like. The transcription/ translation initiation regions corresponding to such structural genes are found immediately 5' upstream to the respective start codons.

In embodiments wherein the expression of the kappa hydroxylase protein is desired in a plant host, the use of all or part of the complete plant kappa hydroxylase gene is desired. If a different promoter is desired, such as a promoter native to the plant host of interest or a modified promoter,

i.e., having transcription initiation regions derived from one gene source and translation initiation regions derived from a different gene source or enhanced promoters, such as double 35S CaMV promoters, the sequences may be joined together using standard techniques.

For such applications when 5' upstream non-coding regions are obtained from other genes regulated during seed maturation, those preferentially expressed in plant embryo tissue, such as transcription initiation control regions from the *B. napus* napin gene, or the *Arabidopsis* 12S storage protein, or soybean β-conglycinin (Bray et al., 1987) are desired. Transcription initiation regions which are preferentially expressed in seed tissue, i.e., which are undetectable in other plant parts, are considered desirable for fatty acid modifications in order to minimize any disruptive or adverse effects of the gene product.

Regulatory transcript termination regions may be provided in DNA constructs of this invention as well. Transcript termination regions may be provided by the DNA sequence encoding the plant kappa hydroxylase or a convenient transcription termination region derived from a different gene source, for example, the transcript termination region which is naturally associated with the transcript initiation region. Where the transcript termination region is from a different gene source, it will contain at least about 0.5 kb, preferably about 1-3 kb of sequence 3' to the structural gene from which the termination region is derived.

Plant expression or transcription constructs having a plant kappa hydroxylase as the DNA sequence

of interest for increased or decreased expression thereof may be employed with a wide variety of plant life, particularly, plant life involved in the production of vegetable oils for edible and industrial uses. Most especially preferred are temperate oilseed crops. Plants of interest include, but are not limited to rapeseed (canola and high erucic acid varieties), *Crambe, Brassica juncea, Brassica nigra*, meadowfoam, flax, sunflower, safflower, cotton, *Cuphea*, soybean, peanut, coconut and oil palms and corn. An important criterion in the selection of suitable plants for the introduction on the kappa hydroxylase is the presence in the host plant of a suitable substrate for the hydroxylase. Thus, for example, production of ricinoleic acid will be best accomplished in plants that normally have high levels of oleic acid in seed lipids. Similarly, production of lesquerolic acid will best be accomplished in plants that have high levels of icosenoic acid in seed lipids.

Depending on the method for introducing the recombinant constructs into the host cell, other DNA sequences may be required. Importantly, this invention is applicable to dicotyledons and monocotyledons species alike and will be readily applicable to new and/or improved transformation and regulation techniques. The method of transformation is not critical to the current invention; various methods of plant transformation are currently available. As newer methods are available to transform crops, they may be directly applied hereunder. For example, many plant species naturally susceptible to *Agrobacterium* infection may be successfully transformed via tripartite or binary

vector methods of *Agrobacterium* mediated transformation. In addition, techniques of microinjection, DNA particle bombardment, electroporation have been developed which allow for the transformation of various monocot and dicot plant species.

In developing the DNA construct, the various components of the construct or fragments thereof will normally be inserted into a convenient cloning vector which is capable of replication in a bacterial host, e.g., *E. coli*. Numerous vectors exist that have been described in the literature. After each cloning, the plasmid may be isolated and subjected to further manipulation, such as restriction, insertion of new fragments, ligation, deletion, insertion, resection, etc., so as to tailor the components of the desired sequence. Once the construct has been completed, it may then be transferred to an appropriate vector for further manipulation in accordance with the manner of transformation of the host cell.

Normally, included with the DNA construct will be a structural gene having the necessary regulatory regions for expression in a host and providing for selection of transformant cells. The gene may provide for resistance to a cytotoxic agent, e.g., antibiotic, heavy metal, toxin, etc., complementation providing prototropy to an auxotrophic host, viral immunity or the like. Depending upon the number of different host species the expression construct or components thereof are introduced, one or more markers may be employed, where different conditions for selection are used for the different hosts.

It is noted that the degeneracy of the DNA code provides that some codon substitutions are permissible of DNA sequences without any corresponding modification of the amino acid sequence.

As mentioned above, the manner in which the DNA construct is introduced into the plant host is not critical to this invention. Any method which provides for efficient transformation may be employed. Various methods for plant cell transformation include the use of Ti- or Ri-plasmids, microinjection, electroporation, infiltration, imbibition, DNA particle bombardment, liposome fusion, DNA bombardment or the like. In many instances, it will be desirable to have the construct bordered on one or both sides of the T-DNA, particularly having the left and right borders, more particularly the right border. This is particularly useful when the construct uses *A. tumefaciens* or *A. rhizogenes* as a mode for transformation, although the T-DNA borders may find use with other modes of transformation.

Where *Agrobacterium* is used for plant cell transformation, a vector may be used which may be introduced into the *Agrobacterium* host for homologous recombination with T-DNA or the Ti- or Ri-plasmid present in the *Agrobacterium* host. The Ti- or Ri-plasmid containing the T-DNA for recombination may be armed (capable of causing gall formation) or disarmed (incapable of causing gall), the latter being permissible, so long as the *vir* genes are present in the transformed *Agrobacterium* host. The armed plasmid can give a mixture of normal plant cells and gall.

In some instances where *Agrobacterium* is used as the vehicle for transforming plant cells, the expression construct bordered by the T-DNA border(s) will be inserted into a broad host spectrum vector, there being broad host spectrum vectors described in the literature. Commonly used is pRK2 or derivatives thereof. See, for example, Ditta et al. (1980), which is incorporated herein by reference. Included with the expression construct and the T-DNA will be one or more markers, which allow for selection of transformed *Agrobacterium* and transformed plant cells. A number of markers have been developed for use with plant cells, such as resistance to kanamycin, the aminoglycoside G418, hygromycin, or the like. The particular marker employed is not essential to this invention, one or another marker being preferred depending on the particular host and the manner of construction.

For transformation of plant cells using *Agrobacterium*, explants may be combined and incubated with the transformed *Agrobacterium* for sufficient time for transformation, the bacteria killed, and the plant cells cultured in an appropriate selective medium. Once callus forms, shoot formation can be encouraged by employing the appropriate plant hormones in accordance with known methods and the shoots transferred to rooting medium for regeneration of plants. The plants may then be grown to seed and the seed used to establish repetitive generations and for isolation of vegetable oils.

Using Hydroxylase Genes to Alter the Activity of Fatty Acid Desaturases

A widely acknowledged goal of current efforts to improve the nutritional quality of edible plant oils, or to facilitate industrial applications of plant oils, is to alter the level of desaturation of plant storage lipids (Topfer et al., 1995). In particular, in many crop species it is considered desirable to reduce the level of polyunsaturation of storage lipids and to increase the level of oleic acid. The precise amount of the various fatty acids in a particular plant oil varies with the intended application. Thus, it is desirable to have a robust method that will permit genetic manipulation of the level of unsaturation to any desired level.

Substantial progress has recently been made in the isolation of genes encoding plant fatty acid desaturases (reviewed in Topfer et al., 1995). These genes have been introduced into various plant species and used to alter the level of fatty acid unsaturation in one of three ways. First, the genes can be placed under transcriptional control of a strong promoter so that the amount of the corresponding enzyme is increased. In some cases this leads to an increase in the amount of the fatty acid that is the product of the reaction catalyzed by the enzyme. For example, Arondel et al. (1992) increased the amount of linolenic acid (18:3) in tissues of transgenic *Arabidopsis* plants by placing the endoplasmic reticulum-localized fad3 gene under transcriptional control of the strong constitutive cauliflower mosaic virus 35S promoter.

A second method of using cloned genes to alter the level of fatty acid unsaturation is to

cause transcription of all or part of a gene in transgenic tissues so that the transcripts have an antisense orientation relative to the normal mode of transcription. This has been used by a number of laboratories to reduce the level of expression of one or more desaturase genes that have significant nucleotide sequence homology to the gene used in the construction of the antisense gene (reviewed in Topfer et al.). For instance, antisense repression of the oleate Δ12-desaturase in transgenic rapeseed resulted in a strong increase in oleic acid content (cf., Topfer et al., 1995).

A third method for using cloned genes to alter fatty acid desaturation is to exploit the phenomenon of cosuppression or "gene-silencing" (Matzke et al., 1995). Although the mechanisms responsible for gene silencing are not known in any detail, it has frequently been observed that in transgenic plants, expression of an introduced gene leads to inactivation of homologous endogenous genes.

For example, high-level sense expression of the *Arabidopsis* fad8 gene, which encodes a chloroplast-localized Δ15-desaturase, in transgenic *Arabidopsis* plants caused suppression of the endogenous copy of the fad8 gene and the homologous fad7 gene (which encodes an isozyme of the fad8 gene) (Gibson et al., 1994). The fad7 and fad8 genes are only 76% identical at the nucleotide level. At the time of publication, this example represented the most divergent pair of plant genes for which cosuppression had been observed.

In view of previous evidence concerning the relatively high level of nucleotide sequence

homology required to obtain cosuppression, it is not obvious to one skilled in the art that sense expression in transgenic plants of the castor fatty acyl hydroxylase of this invention would significantly alter the amount of unsaturation of storage lipids.

However, the present inventors establish that fatty acyl hydroxylase genes can be used for this purpose as taught in Example 4 of this specification. Of particular importance, this invention teaches the use of fatty acyl hydroxylase genes to increase the proportion of oleic acid in transgenic plant tissues. The mechanism by which expression of the gene exerts this effect is not known but may be due to one of several possibilities which are elaborated upon in Example 4.

The invention now being generally described, it will be more readily understood by reference to the following examples which are included for purposes of illustration only and are not intended to limit the present invention.

EXAMPLES

In the experimental disclosure which follows, all temperatures are given in degrees centigrade (°C), weights are given in grams (g), milligram (mg) or micrograms (μg), concentrations are given as molar (M), millimolar (mM) or micromolar (μM) and all volumes are given in liters (l), microliters (μl) or milliliters (ml), unless otherwise indicated.

EXAMPLE 1 - PRODUCTION OF NOVEL HYDROXYLATED FATTY ACIDS IN *ARABIDOPSIS THALIANA*

Overview

The kappa hydroxylase encoded by the fah12 gene from castor was used to produce ricinoleic acid, lesquerolic acid, densipolic acid and auricolic acid in transgenic *Arabidopsis* plants.

Production of transgenic plants

A variety of methods have been developed to insert a DNA sequence of interest into the genome of a plant host to obtain the transcription and translation of the sequence to effect phenotypic changes. The following methods represent only one of many equivalent means of producing transgenic plants and causing expression of the hydroxylase gene.

Arabidopsis plants were transformed, by *Agrobacterium*-mediated transformation, with the kappa hydroxylase encoded by the castor fah12 gene on binary Ti plasmid pB6. This plasmid has also been used to transform *Nicotiana tabacum* for the production of ricinoleic acid.

Inoculums of *Agrobacterium tumefaciens* strain GV3101 containing binary Ti plasmid pB6 were plated on L-broth plates containing 50 µg/ml kanamycin and incubated for 2 days at 30°C. Single colonies were used to inoculate large liquid cultures (L-broth medium with 50 mg/l rifampicin, 110 mg/l gentamycin and 200 mg/l kanamycin) to be used for the transformation of *Arabidopsis* plants.

Arabidopsis plants were transformed by the *in planta* transformation procedure essentially as described by Bechtold et al. (1993). Cells of *A. tumefaciens* GV3101(pB6) were harvested from liquid

cultures by centrifugation, then resuspended in infiltration medium at OD_{600} = 0.8. Infiltration medium was Murashige and Skoog macro and micronutrient medium (Sigma Chemical Co., St. Louis, MO) containing 10 mg/l 6-benzylaminopurine and 5% glucose. Batches of 12-15 plants were grown for 3 to 4 weeks in natural light at a mean daily temperature of approximately 25°C in 3.5 inch pots containing soil. The intact plants were immersed in the bacterial suspension then transferred to a vacuum chamber and placed under 600 mm of vacuum produced by a laboratory vacuum pump until tissues appeared uniformly water-soaked (approximately 10 min). The plants were grown at 25°C under continuous light (100 μmol m^{-2} s^{-1} irradiation in the 400 to 700 nm range) for four weeks. The seeds obtained from all the plants in a pot were harvested as one batch. The seeds were sterilized by sequential treatment for 2 min with ethanol followed by 10 min in a mixture of household bleach (Chlorox), water and Tween-80 (50%, 50%, 0.05%) then rinsed thoroughly with sterile water. The seeds were plated at high density (2000 to 4000 per plate) onto agar-solidified medium in 100 mm petri plates containing 1/2 X Murashige and Skoog salts medium enriched with B5 vitamins (Sigma Chemical Co., St. Louis, MO) and containing kanamycin at 50 mg/l. After incubation for 48 h at 4°C to stimulate germination, seedlings were grown for a period of seven days until transformants were clearly identifiable as healthy green seedlings against a background of chlorotic kanamycin-sensitive seedlings. The transformants were transferred to soil for two weeks before leaf tissue

could be used for DNA and lipid analysis. More than 20 transformants were obtained.

DNA was extracted from young leaves from transformants to verify the presence of an intact fah12 gene. The presence of the transgene in a number of the putative transgenic lines was verified by using the polymerase chain reaction to amplify the insert from pB6. The primers used were HF2 = GCTCTTTTGTGCGCTCATTC (SEQ ID NO:12) and HR1 = CGGTACCAGAAAACGCCTTG (SEQ ID NO:13), which were designed to allow the amplification of a 700 bp fragment. Approximately 100 ng of genomic DNA was added to a solution containing 25 pmol of each primer, 1.5 U Taq polymerase (Boehringer Manheim), 200 uM of dNTPs, 50 mM KCl, 10 mM Tris.Cl (pH 9), 0.1% (v/v) Triton X-100, 1.5 mM $MgCl_2$, 3% (v/v) formamide, to a final volume of 50 μl. Amplifications conditions were: 4 min denaturation step at 94°C, followed by 30 cycles of 92°C for 1 min, 55°C for 1 min, 72°C for 2 min. A final extension step closed the program at 72°C for 5 min. Transformants could be positively identified after visualization of a characteristic 1 kb amplified fragment on an ethidium bromide stained agarose gel. All transgenic lines tested gave a PCR product of a size consistent with the expected genotype, confirming that the lines were, indeed, transgenic. All further experiments were done with three representative transgenic lines of the wild type designated as 1-3, 4D, 7-4 and one transgenic line of the fad2 mutant line JB12. The transgenic JB12 line was included in order to test whether the increased accumulation of oleic acid in this mutant

would have an effect on the amount of ricinoleic acid that accumulated in the transgenic plants.

Analysis of transgenic plants

Leaves and seeds from fah12 transgenic *Arabidopsis* plants were analyzed for the presence of hydroxylated fatty acids using gas chromatography. Lipids were extracted from 100-200 mg leaf tissue or 50 seeds. Fatty acid methyl esters (FAMES) were prepared by placing tissue in 1.5 ml of 1.0 M methanolic HCl (Supelco Co.) in a 13 x 100 mm glass screw-cap tube capped with a teflon-lined cap and heated to 80°C for 2 hours. Upon cooling, 1 ml petroleum ether was added and the FAMES removed by aspirating off the ether phase which was then dried under a nitrogen stream in a glass tube. One hundred μl of N,O-bis(Trimethylsilyl) trifluoroacetamide (BSTFA; Pierce Chemical Co) and 200 μl acetonitrile was added to derivatize the hydroxyl groups. The reaction was carried out at 70°C for 15 min. The products were dried under nitrogen, redissolved in 100 μl chloroform and transferred to a gas chromatograph vial. Two μl of each sample were analyzed on a SP2340 fused silica capillary column (30 m, 0.75 mm ID, 0.20 mm film, Supelco), using a Hewlett-Packard 5890 II series Gas Chromatograph. The samples were not split, the temperature program was 195°C for 18 min, increased to 230°C at 25°C/min, held at 230°C for 5 min then down to 195°C at 25°C/min., and flame ionization detectors were used.

The chromatographic elution time of methyl esters and O-TMS derivatives of ricinoleic acid, lesquerolic acid and auricolic acid was established

by GC-MS of lipid samples from seeds of *L. fendleri* and comparison to published chromatograms of fatty acids from this species (Carlson et al., 1990). A O-TMS-methyl-ricinoleate standard was prepared from ricinoleic acid obtained from Sigma Chemical Co (St, Louis, MO). O-TMS-methyl-lesqueroleate and O-TMS-methyl-auricoleate standards were prepared from triacylglycerols purified from seeds of *L. fendleri*. The mass spectrum of O-TMS-methyl-ricinoleate, O-TMS-methyl-densipoleate, O-TMS-methyl-lesqueroleate, and O-TMS-methyl-auricoleate are shown in Figures 1A-D, respectively. The structures of the characteristic ions produced during mass spectrometry of these derivatives are shown in Figure 2.

Lipid extracted from transgenic tissues were analyzed by gas chromatography and mass spectrometry for the presence of hydroxylated fatty acids. As a matter of reference, the average fatty acid composition of leaves in *Arabidopsis* wild type and fad2 mutant lines was reported by Miquel and Browse (1992). Gas chromatograms of methylated and silylated fatty acids from seeds of wild type and a fah12 transgenic wild type plant are shown in Figures 3A and 3B, respectively. The profiles are very similar except for the presence of three small but distinct peaks at 14.3, 15.9 and 18.9 minutes. A very small peak at 20.15 min was also evident. The elution time of the peaks at 14.3 and 18.9 min corresponded precisely to that of comparably prepared ricinoleic and lesquerolic standards, respectively. No significant differences were observed in lipid extracts from leaves or roots of

the wild type and the fah12 transgenic wild type lines (Table 1).

Thus, in spite of the fact that the fah12 gene is expressed throughout the plant, effects on fatty acid composition was observed only in seed tissue. The present inventors have made a similar observation for transgenic fah12 tobacco.

Table 1. Fatty acid composition of lipids from transgenic and wild type *Arabidopsis*. The values are the means obtained from analysis of samples from three independent transgenic lines, or three independent samples of wild type and fad2 lines.

20:2-OH	0	0.1	0.1	0	0	0	0	0

In order to confirm that the observed new peaks in the transgenic lines corresponded to derivatives of ricinoleic, lesquerolic, densipolic and auricolic acids, mass spectrometry was used. The fatty acid derivatives were resolved by gas chromatography as described above except that a Hewlett-Packard 5971 series mass selective detector was used in place of the flame ionization detector used in the previous experiment. The spectra of the four new peaks in Figure 3B (peak numbers 10, 11, 12 and 13) are shown in Figures 4A-D, respectively. Comparison of the spectrum obtained for the standards with that obtained for the four peaks from the transgenic lines confirms the identity of the four new peaks. On the basis of the three characteristic peaks at M/Z 187, 270 and 299, peak 10 is unambiguously identified as O-TMS-methylricinoleate. On the basis of the three characteristic peaks at M/Z 185, 270 and 299, peak 11 is unambiguously identified as O-TMS-methyldensipoleate. On the basis of the three characteristic peaks at M/Z 187, 298 and 327, peak 12 is unambiguously identified as O-TMS-methyllesqueroleate. On the basis of the three characteristic peaks at M/Z 185, 298 and 327, peak 13 is unambiguously identified as O-TMS-methylauricoleate.

These results unequivocally demonstrate the identity of the fah12 cDNA as encoding a hydroxylase that hydroxylates both oleic acid to produce ricinoleic acid and also hydroxylates icosenoic acid to produce lesquerolic acid. These results also provide additional evidence that the hydroxylase can be functionally expressed in a heterologous plant

species in such a way that the enzyme is catalytically functional. These results also demonstrate that expression of this hydroxylase gene leads to accumulation of ricinoleic, lesquerolic, densipolic and auricolic acids in a plant species that does not normally accumulate hydroxylated fatty acids in extractable lipids.

The present inventors expected to find lesquerolic acid in the transgenic plants based on the biochemical evidence suggesting broad substrate specificity of the kappa hydroxylase. By contrast, the accumulation of densipolic and auricolic acids was less predictable. Since *Arabidopsis* does not normally contain significant quantities of the non-hydroxylated precursors of these fatty acids which could serve as substrates for the hydroxylase, it appears that one or more of the three n-3 fatty acid desaturases known in *Arabidopsis* (e.g., fad3, fad7, fad8; reviewed in Gibson et al., 1995) are capable of desaturating the hydroxylated compounds at the n-3 position. That is, densipolic acid is produced by the action of an n-3 desaturase on ricinoleic acid. Auricolic acid is produced by the action of an n-3 desaturase on lesquerolic acid. Because it is located in the endoplasmic reticulum, the fad3 desaturase is almost certainly responsible. This can be tested in the future by producing fah12-containing transgenic plants of the fad3-deficient mutant of *Arabidopsis* (similar experiments can be done with fad7 and fad8). It is also formally possible that the enzymes that normally elongate $18{:}1^{cis\Delta9}$ to $20{:}1^{cis\Delta11}$ may elongate $12OH\text{-}18{:}1^{cis\Delta9}$ to $14OH\text{-}20{:}1^{cis\Delta11}$, and $12OH\text{-}18{:}2^{cis\Delta9,15}$ to $14OH\text{-}20{:}2^{cis\Delta11,17}$.

The amount of the various fatty acids in seed, leaf and root lipids of the control and transgenic plants is also presented in Table 1. Although the amount of hydroxylated fatty acids produced in this example is less than desired for production of ricinoleate and other hydroxylated fatty acids from plants, numerous improvements may be envisioned that will increase the level of accumulation of hydroxylated fatty acids in plants that express the fah12 or related hydroxylase genes. Improvements in the level and tissue specificity of expression of the hydroxylase gene are envisioned. Methods to accomplish this by the use of strong, seed-specific promoters such as the *B. napus* napin promoter will be obvious to one skilled in the art. Additional improvements are envisioned that involve modification of the enzymes which cleave hydroxylated fatty acids from phosphatidylcholine, reduction in the activities of enzymes which degrade hydroxylated fatty acids and replacement of acyltransferases which transfer hydroxylated fatty acids to the sn-1, sn-2 and sn-3 positions of glycerolipids. Although genes for these enzymes have not been described in the scientific literature, their utility in improving the level of production of hydroxylated fatty acids can be readily appreciated based on the results of biochemical investigations of ricinoleate synthesis.

Although *Arabidopsis* is not an economically important plant species, it is widely accepted by plant biologists as a model for higher plants. Therefore, the inclusion of this example is intended to demonstrate the general utility of the invention described here to the modification of oil

composition in higher plants. One advantage of studying the expression of this novel gene in *Arabidopsis* is the existence in this system of a large body of knowledge on lipid metabolism, as well as the availability of a collection of mutants which can be used to provide useful information on the biochemistry of fatty acid hydroxylation in plant species. Another advantage is the ease of transposing any of the information obtained on metabolism of ricinoleate in *Arabidopsis* to closely related species such as the crop plants *Brassica napus, Brassica juncea* or *Crambe abyssinica* in order to mass produce ricinoleate, lesqueroleate or other hydroxylated fatty acids for industrial use. The kappa hydroxylase is useful for the production of ricinoleate or lesqueroleate in any plant species that accumulates significant levels of the precursors, oleic acid and icosenoic acid. Of particular interest are genetically modified varieties that accumulate high levels of oleic acid. Such varieties are currently available for sunflower and canola. Production of lesquerolic acid and related hydroxy fatty acids can be achieved in species that accumulate high levels of icosenoic acid or other long chain monoenoic acids. Such plants may in the future be produced by genetic engineering of plants that do not normally make such precursors. Thus, the use of the kappa hydroxylase will be of general utility.

EXAMPLE 2. ISOLATION OF *LESQUERELLA* KAPPA HYDROXYLASE GENOMIC CLONE

Overview

Regions of nucleotide sequence that were conserved in both the castor kappa hydroxylase and the *Arabidopsis* fad2 Δ12 fatty acid desaturase were used to design oligonucleotide primers. These were used with genomic DNA from *Lesquerella fendleri* to amplify fragments of several homologous genes. These amplified fragments were then used as hybridization probes to identify full length genomic clones from a genomic library of *L. fendleri*.

Hydroxylated fatty acids are specific to the seed tissue of *Lesquerella* sp., and are not found to any appreciable extent in vegetative tissues. One of the two genes identified by this method was expressed in both leaves and developing seeds and is therefore thought to correspond to the Δ12 fatty acid desaturase. The other gene was expressed at high levels in developing seeds but was not expressed or was expressed at very low levels in leaves and is the kappa hydroxylase from this species. The identity of the gene as a fatty acyl hydroxylase was established by functional expression of the gene in yeast.

The identity of this gene will also be established by introducing the gene into transgenic *Arabidopsis* plants and showing that it causes the accumulation of ricinoleic acid, lesquerolic acid, densipolic acid and auricolic acid in seed lipids.

The various steps involved in this process are described in detail below. Unless otherwise indicated, routine methods for manipulating nucleic

acids, bacteria and phage were as described by Sambrook et al. (1989).

Isolation of a fragment of the *Lesquerella* kappa hydroxylase gene

Oligonucleotide primers for the amplification of the *L. fendleri* kappa hydroxylase were designed by choosing regions of high deduced amino acid sequence homology between the castor kappa hydroxylase and the *Arabidopsis* Δ12 desaturase (fad2). Because most amino acids are encoded by several different codons, these oligonucleotides were designed to encode all possible codons that could encode the corresponding amino acids.

The sequence of these mixed oligonucleotides was Oligo 1: TAYWSNCAYMGNMGNCAYCA (SEQ ID NO:14) and Oligo 2: RTGRTGNGCNACRTGNGTRTC (SEQ ID NO:15) where Y = C+T, W = A+T, S = G+C, N = A+G+C+T, M = A+C, and R = A+G.

These oligonucleotides were used to amplify a fragment of DNA from *L. fendleri* genomic DNA by the polymerase chain reaction (PCR) using the following conditions: Approximately 100 ng of genomic DNA was added to a solution containing 25 pmol of each primer, 1.5 U Taq polymerase (Boehringer Manheim), 200 uM of dNTPs, 50 mM KCl, 10 mM Tris.Cl (pH 9), 0.1% (v/v) Triton X-100, 1.5 mM $MgCl_2$, 3% (v/v) formamide, to a final volume of 50 μl. Amplifications conditions were: 4 min denaturation step at 94°C, followed by 30 cycles of 92°C for 1 min, 55°C for 1 min, 72°C for 2 min. A final extension step closed the program at 72°C for 5 min.

PCR products of approximately 540 bp were observed following electrophoretic separation of the

products of the PCR reaction in agarose gels. Two of these fragments were cloned into pBluescript (Stratagene) to give rise to plasmids pLesq2 and pLesq3. The sequence of the inserts in these two plasmids was determined by the chain termination method. The sequence of the insert in pLesq2 is presented as Figure 5 (SEQ ID NO:1) and the sequence of the insert in pLesq3 is presented as Figure 6 (SEQ ID NO:2). The high degree of sequence identity between the two clones indicated that they were both potential candidates to be either a Δ12 desaturase or a kappa hydroxylase.

<u>Northern analysis</u>

In *L. fendleri*, hydroxylated fatty acids are found in large amounts in seed oils but are not found in appreciable amounts in leaves. An important criterion in discriminating between a fatty acyl desaturase and kappa hydroxylase is that the kappa hydroxylase gene is expected to be expressed more highly in tissues which have high level of hydroxylated fatty acids than in other tissues. In contrast, all plant tissues should contain mRNA for an ω6 fatty acyl desaturase since diunsaturated fatty acids are found in the lipids of all tissues in most or all plants.

Therefore, it was of great interest to determine whether the gene corresponding to pLesq2 was also expressed only in seeds, or is also expressed in other tissues. This question was addressed by testing for hybridization of pLesq2 to RNA purified from developing seeds and from leaves.

Total RNA was purified from developing seeds and young leaves of *L. fendleri* using an Rneasy RNA

extraction kit (Qiagen), according to the manufacturer's instructions. RNA concentrations were quantified by UV spectrophotometry at λ=260 and 280 nm. In order to ensure even loading of the gel to be used for Northern blotting, RNA concentrations were further adjusted after recording fluorescence under UV light of RNA samples stained with ethidium bromide and run on a test denaturing gel.

Total RNA prepared as described above from leaves and developing seeds was electrophoresed through an agarose gel containing formaldehyde (Iba et al., 1993). An equal quantity (10 μg) of RNA was loaded in both lanes, and RNA standards (0.16-1.77 kb ladder, Gibco-BRL) were loaded in a third lane. Following electrophoresis, RNA was transferred from the gel to a nylon membrane (Hybond N+, Amersham) and fixed to the filter by exposure to UV light.

A ^{32}P-labelled probe was prepared from insert DNA of clone pLesq2 by random priming and hybridized to the membrane overnight at 52°C, after it had been prehybridized for 2 h. The prehybridization solution contained 5X SSC, 10X Denhardt's solution, 0.1% SDS, 0.1M KPO_4 pH 6.8, 100 μg/ml salmon sperm DNA. The hybridization solution had the same basic composition, but no SDS, and it contained 10% dextran sulfate and 30% formamide. The blot was washed once in 2X SSC, 0.5% SDS at 65°C then in 1X SSC at the same temperature.

Brief (30 min) exposure of the blot to X-ray film revealed that the probe pLesq2 hybridized to a single band only in the seed RNA lane (Figure 7). The blot was re-probed with the insert from pLesq3 gene, which gave bands of similar intensity in the seed and leaf lanes (Figure 7).

These results show that the gene corresponding to the clone pLesq2 is highly and specifically expressed in seed of *L. fendleri*. In conjunction with knowledge of the nucleotide and deduced amino acid sequence, strong seed-specific expression of the gene corresponding to the insert in pLesq2 is a convincing indicator of the role of the enzyme in synthesis of hydroxylated fatty acids in the seed oil.

Characterization of a genomic clone of the kappa hydroxylase

Genomic DNA was prepared from young leaves of *L. fendleri* as described by Murray and Thompson (1980). A *Sau3A*I-partial digest genomic library constructed in the vector λDashII (Stratagene, 11011 North Torrey Pines Road, La Jolla CA 92037) was prepared by partially digesting 500 μg of DNA, size-selecting the DNA on a sucrose gradient (Sambrook et al., 1989), and ligating the DNA (12 kb average size) to the *BamH*I-digested arms of λDashII. The entire ligation was packaged according to the manufacturer's conditions and plated on *E. coli* strain XL1-Blue MRA-P2 (Stratagene). This yielded $5x10^5$ primary recombinant clones. The library was then amplified according to the manufacturer's conditions. A fraction of the genomic library was plated on *E. coli* XL1-Blue and resulting plaques (150,000) were lifted to charged nylon membranes (Hybond N+, Amersham), according to the manufacturer's conditions. DNA was crosslinked to the filters under UV in a Stratalinker (Stratagene).

Several clones carrying genomic sequences corresponding to the *L. fendleri* hydroxylase were

isolated by probing the membranes with the insert from pLesq2 that was PCR-amplified with internal primers and labelled with ^{32}P by random priming. The filters were prehybridized for 2 hours at 65°C in 7% SDS, 1mM EDTA, 0.25 M Na_2HPO_4 (pH 7.2), 1% BSA and hybridized to the probe for 16 hours in the same solution. The filters were sequentially washed at 65°C in solutions containing 2 X SSC, 1 X SSC, 0.5 X SSC in addition to 0.1 % SDS. A 2.6 kb *Xba*I fragment containing the complete coding sequence for the kappa hydroxylase and approximately 1 kb of the 5' upstream region was subcloned into the corresponding site of pBluescript KS to produce plasmid pLesq-Hyd and the sequence determined completely using an automatic sequencer by the dideoxy chain termination method. Sequence data was analyzed using the program DNASIS (Hitachi Company).

The sequence of the insert in clone pLesq-Hyd is shown in Figures 8A-B. The sequence entails 1855 bp of contiguous DNA sequence (SEQ ID NO:3). The clone encodes a 401 bp 5' untranslated region (i.e., nucleotides preceding the first ATG codon), an 1152 bp open reading frame, and a 302 bp 3' untranslated region. The open reading frame encodes a 384 amino acid protein with a predicted molecular weight of 44,370 (SEQ ID NO:4). The amino terminus lacks features of a typical signal peptide (von Heijne, 1985).

The exact translation-initiation methionine has not been experimentally determined, but on the basis of deduced amino acid sequence homology to the castor kappa hydroxylase (noted below) is thought to be the methionine encoded by the first ATG codon at nucleotide 402.

Comparison of the pLesq-Hyd deduced amino acid sequence with sequences of membrane-bound desaturases and the castor hydroxylase (Figures 9A-B) indicates that pLesq-Hyd is homologous to these genes. This figure shows an alignment of the *L. fendleri* hydroxylase (SEQ ID NO:4) with the castor hydroxylase (van de Loo et al., 1995), the *Arabidopsis fad2* cDNA which encodes an endoplasmic reticulum-localized Δ12 desaturase (called fad2) (Okuley et al., 1994), two soybean fad2 desaturase clones, a *Brassica napus* fad2 clone, a *Zea mays* fad2 clone and partial sequence of a *R. communis* fad2 clone.

The high degree of sequence homology indicates that the gene products are of similar function. For instance, the overall homology between the *Lesquerella* hydroxylase and the *Arabidopsis* fad2 desaturase was 92.2% similarity and 84.8% identity and the two sequences differed in length by only one amino acid.

Southern hybridization

Southern analysis was used to examine the copy number of the genes in the *L. fendleri* genome corresponding to the clone pLesq-Hyd. Genomic DNA (5 μg) was digested with *Eco*RI, *Hin*dIII and *Xba*I and separated on a 0.9% agarose gel. DNA was alkali-blotted to a charged nylon membrane (Hybond N+, Amersham), according to the manufacturer's protocol. The blot was prehybridized for 2 hours at 65°C in 7% SDS, 1mM EDTA, 0.25 M Na_2HPO_4 (pH 7.2), 1% BSA and hybridized to the probe for 16 hours in the same solution with pLesq-Hyd insert PCR-amplified with internal primers and labelled with ^{32}P by random

priming. The filters were sequentially washed at 65°C in solutions containing 2 X SSC, 1 X SSC, 0.5 X SSC in addition to 0.1 % SDS, then exposed to X-ray film.

The probe hybridized with a single band in each digest of *L. fendleri* DNA (Figure 10), indicating that the gene from which pLesq-Hyd was transcribed is present in a single copy in the *L. fendleri* genome.

<u>Expression of pLesq-Hyd in Transgenic Plants</u>

There are a wide variety of plant promoter sequences which may be used to cause tissue-specific expression of cloned genes in transgenic plants. For instance, the napin promoter and the acyl carrier protein promoters have previously been used in the modification of seed oil composition by expression of an antisense form of a desaturase (Knutson et al., 1992). Similarly, the promoter for the β-subunit of soybean β-conglycinin has been shown to be highly active and to result in tissue-specific expression in transgenic plants of species other than soybean (Bray et al., 1987). Thus, other promoters which lead to seed-specific expression may also be employed for the production of modified seed oil composition. Such modifications of the invention described here will be obvious to one skilled in the art.

Constructs for expression of *L. fendleri* kappa hydroxylase in plant cells are prepared as follows: A 13 kb *Sal*I fragment containing the pLesq-Hyg gene was ligated into the *Xho*I site of binary Ti plasmid vector pSLJ44026 (Jones et al., 1992) (Figure 11) to produce plasmid pTi-Hyd and

transformed into *Agrobacterium tumefaciens* strains GV3101 by electroporation. Strain GV3101 (Koncz and Schell, 1986) contains a disarmed Ti plasmid. Cells for electroporation were prepared as follows. GV3101 was grown in LB medium with reduced NaCl (5 g/l). A 250 ml culture was grown to OD_{600} = 0.6, then centrifuged at 4000 rpm (Sorvall GS-A rotor) for 15 min. The supernatant was aspirated immediately from the loose pellet, which was gently resuspended in 500 ml ice-cold water. The cells were centrifuged as before, resuspended in 30 ml ice-cold water, transferred to a 30 ml tube and centrifuged at 5000 rpm (Sorvall SS-34 rotor) for 5 min. This was repeated three times, resuspending the cells consecutively in 30 ml ice-cold water, 30 ml ice-cold 10% glycerol, and finally in 0.75 ml ice-cold 10% glycerol. These cells were aliquoted, frozen in liquid nitrogen, and stored at -80°C.

Electroporations employed a Biorad Gene Pulser instrument using cold 2 mm-gap cuvettes containing 40 μl cells and 1 μl of DNA in water, at a voltage of 2.5 KV, and 200 Ohms resistance. The electroporated cells were diluted with 1 ml SOC medium (Sambrook et al., 1989, page A2) and incubated at 28°C for 2-4 h before plating on medium containing kanamycin (50 mg/l).

Arabidopsis thaliana can be transformed with the *Agrobacterium* cells containing pTi-Hyd as described in Example 1 above. Similarly, the presence of hydroxylated fatty acids in the transgeneic *Arabidopsis* plants can be demonstrated by the methods described in Example 1 above.

Constitutive expression of the *L. fendleri* hydroxylase in transgenic plants

A 1.5 kb *Eco*RI fragment from pLesq-Hyg comprising the entire coding region of the hydroxylase was gel purified, then cloned into the corresponding site of pBluescript KS (Stratagene). Plasmid DNA from a number of recombinant clones was then restricted with *Pst*I, which should cut only once in the insert and once in the vector polylinker sequence. Release of a 920 bp fragment with *Pst*I indicated the right orientation of the insert for further manipulations. DNA from one such clone was further restricted with *Sal*I, the 5′ overhangs filled-in with the Klenow fragment of DNA polymerase I, then cut with *Sac*I. The insert fragment was gel purified, and cloned between the *Sma*I and *Sac*I sites of pBI121 (Clontech) behind the cauliflower mosaic virus 35S promoter. After checking that the sequence of the junction between insert and vector DNA was appropriate, plasmid DNA from a recombinant clone was used to transform *A. tumefaciens* (GV3101). Kanamycin resistant colonies were then used for *in planta* transformation of *A. thaliana* as previously described.

DNA was extracted from kanamycin resistant seedlings and used to PCR-amplify selected fragments from the hydroxylase using nested primers. When fragments of the expected size could be amplified, corresponding plants were grown in the greenhouse or on agar plates, and fatty acids extracted from fully expanded leaves, roots and dry seeds. GC-MS analysis was then performed as previously described to characterize the different fatty acid species and

detect accumulation of hydroxy fatty acids in transgenic tissues.

<u>Expression of the *Lesquerella* hydroxylase in yeast</u>

In order to demonstrate that the cloned *L. fendleri* gene encoded a kappa hydroxylase, the gene was expressed in yeast cells under transcriptional control of an inducible promoter and the yeast cells were examined for the presence of hydroxylated fatty acids by GC-MS.

In a first step, a lambda genomic clone containing the *L. fendleri* hydroxylase gene was cut with *Eco*RI, and a resulting 1400 bp fragment containing the coding sequence of the hydroxylase gene was subcloned in the *Eco*RI site of the pBluescript KS vector (Stratagene). This subclone, pLesqcod, contains the coding region of the *Lesquerella* hydroxylase plus some additional 3' sequence.

In a second step, pLesqcod was cut with *Hin*dIII and *Xba*I, and the insert fragment was cloned into the corresponding sites of the yeast expression vector pYes2 (Invitrogen; Figure 12). This subclone, pLesqYes, contains the *L. fendleri* hydroxylase in the sense orientation relative to the 3' side of the Gal1 promoter. This promoter is inducible by the addition of galactose to the growth medium, and is repressed upon addition of glucose. In addition, the vector carries origins of replication allowing the propagation of pLesqYes in both yeast and *E. coli*.

<u>Transformation of *S. cerevisiae* host strain CGY2557</u>

Yeast strain CGY2557 (*MATα*, GAL⁺, *ura3-52, leu2-3, trp1, ade2-1, lys2-1, his5, can1-100*) was

grown overnight at 28°C in YPD liquid medium (10 g yeast extract, 20 g bacto-peptone, 20 g dextrose per liter), and an aliquot of the culture was inoculated into 100 ml fresh YPD medium and grown until the OD_{600} of the culture was 1. Cells were then collected by centrifugation and resuspended in about 200μl of supernatant. 40μl aliquots of the cell suspension were then mixed with 1-2μg DNA and electroporated in 2 mm-gap cuvettes using a Biorad Gene Pulser instrument set at 600 V, 200 Ω, 25 μF, 160μl YPD was added and the cells were plated on selective medium containing glucose. Selective medium consisted of 6.7 g yeast nitrogen base (Difco), 0.4 g casamino acids (Difco), 0.02 g adenine sulfate, 0.03 g L-leucine, 0.02 g L-tryptophan, 0.03 g L-lysine-HCl, 0.03 g L-histidine-HCl , 2% glucose, water to 1 liter. Plates were solidified using 1.5% Difco Bacto-agar. Transformant colonies appeared after 3 to 4 days incubation at 28°C.

Expression of the *L. fendleri* hydroxylase in yeast

Independent transformant colonies from the previous experiment were used to inoculate 5 ml of selective medium containing either 2% glucose (gene repressed) or 2% galactose (gene induced) as the sole carbon source. Independent colonies of CGY2557 transformed with pYES2 containing no insert were used as controls.

After 2 days of growth at 28°C, an aliquot of the cultures was used to inoculate 5 ml of fresh selective medium. The new culture was placed at 16°C and grown for 9 days.

Fatty acid analysis of yeast expressing the *L. fendleri* hydroxylase

Cells from 2.5 ml of culture were pelleted at 1800g, and the supernatant was aspirated as completely as possible. Pellets were then dispersed in 1 ml of 1 N methanolic HCl (Supelco, Bellafonte, PA). Transmethylation and derivatization of hydroxy fatty acids were performed as described above. After drying under nitrogen, samples were redissolved in 50µl chloroform before being analyzed by GC-MS. Samples were injected into an SP2330 fused-silica capillary column (30 m x 0.25 mm ID, 0.25µm film thickness, Supelco). The temperature profile was 100 - 160°C, 25°C/min, 160 - 230°C, 10°C/min, 230°C, 3 min, 230-100°C, 25°C/min. Flow rate was 0.9 ml/min. Fatty acids were analyzed using a Hewlett-Packard 5971 series Msdetector.

Gas chromatograms of derivatized fatty acid methyl esters from induced cultures of yeast containing pLesqYes contained a novel peak that eluted at 7.6 min (Figure 13). O-TMS methyl ricinoleate eluted at exactly the same position on control chromatograms. This peak was not present in cultures lacking pLesqYes or in cultures containing pLesqYes grown on glucose (repressing conditions) rather than galactose (inducing conditions). Mass spectrometry of the peak (Figure 13) revealed that the peak has the same spectrum as O-TMS methyl ricinoleate. Thus, on the basis of chromatographic retention time and mass spectrum, it was concluded that the peak corresponded to O-TMS methyl ricinoleate. The presence of ricinoleate in the transgenic yeast cultures confirms the identity of the gene as a kappa hydroxylase of this invention.

EXAMPLE 3. OBTAINING OTHER PLANT FATTY ACYL HYDROXYLASES

The castor fah12 sequence could be used to identify other kappa hydroxylases by methods such as PCR and heterologous hybridization. However, because of the high degree of sequence similarity between Δ12 desaturases and kappa hydroxylases, the prior art does not teach how to distinguish between the two kinds of enzymes without a functional test such as demonstrating activity in transgenic plants or another suitable host (e.g., transgenic microbial or animal cells). The identification of the *L. fendleri* hydroxylase provided for the development of criteria by which a hydroxylase and a desaturase may be distinguished solely on the basis of deduced amino acid sequence information.

Figures 9A-B show a sequence alignment of the castor and *L. fendleri* hydroxylase sequences with the castor hydroxylase sequence and all publicly available sequences for all plant microsomal Δ12 fatty acid desaturases. Of the 384 amino acid residues in the castor hydroxylase sequence, more than 95% are identical to the corresponding residue in at least one of the desaturase sequences. Therefore, none of these residues are responsible for the catalytic differences between the hydroxylase and the desaturases. Of the remaining 16 residues in the castor hydroxylase and 14 residues in the *Lesquerella* hydroxylase, all but seven represent instances where the hydroxylase sequence has a conservative substitution compared with one or more of the desaturase sequences, or there is wide variability in the amino acid at that position in the various desaturases. By conservative, it is

meant that the following amino acids are functionally equivalent: Ser/Thr, Ile/Leu/Val/Met, Asp/Glu. Thus, these structural differences also cannot account for the catalytic differences between the desaturases and hydroxylases. This leaves just seven amino acid residues where both the castor hydroxylase and the *Lesquerella* hydroxylase differ from all of the known desaturases and where all of the known microsomal Δ12 desaturases have the identical amino acid residue. These residues occur at positions 69, 111, 155, 226, 304, 331 and 333 of the alignment in Figure 9. Therefore, these seven sites distinguish hydroxylases from desaturases. Based on this analysis, the present inventors believe that any enzyme with greater than 60% sequence identity to one of the enzymes listed in Figure 9 can be classified as a hydroxylase if it differs from the sequence of the desaturases at these seven positions. Because of slight differences in the number of residues in a particular protein, the numbering may vary from protein to protein but the intent of the number system will be evident if the protein in question is aligned with the castor hydroxylase using the numbering system shown herein. Thus, in conjunction with the methods for using the *Lesquerella* hydroxylase gene to isolate homologous genes, the structural criterion disclosed here teaches how to isolate and identify plant kappa hydroxylase genes for the purpose of genetically modifying fatty acid composition as disclosed herein.

EXAMPLE 4 - USING HYDROXYLASES TO ALTER THE LEVEL OF FATTY ACID UNSATURATION

Evidence that kappa hydroxylases of this invention can be used to alter the level of fatty acid unsaturation was obtained from the analysis of transgenic plants that expressed the castor hydroxylase under control of the cauliflower mosaic virus promoter. The construction of the plasmids and the production of transgenic *Arabidopsis* plants was described in Example 1 (above). The fatty acid composition of seed lipids from wild type and six transgenic lines (1-2/a, 1-2/b, 1-3/b, 4F, 7E, 7F) is shown in Table 2.

Table 2. Fatty acid composition of lipids from *Arabidopsis* seeds. The asterisk (*) indicates that for some of these samples, the 18:3 and 20:1 peaks overlapped on the gas chromatograph and, therefore, the total amount of these two fatty acids is reported.

TABLE 2

Fatty acid	WT	1-2/a	1-2/b	1-3/b	4F	7E	7F
16:0	10.3	8.6	9.5	8.4	8.1	8.4	9
18:0	3.5	3.8	3.9	3.3	3.5	3.8	4.2
18:1	14.7	33	34.5	25.5	27.5	30.5	28.5
18:2	32.4	16.9	21	27.5	21.1	20.1	19.8
18:3	13.8	-	14.4	14.8	-	-	-
20:0	1.3	1.6	1	1.1	2.4	1.8	2
20:1	22.5	-	14.1	17.5	-	-	-
18:3 20:1*	-	31.2	-	-	32.1	30.8	30.6
Ricinoleic	0	0.6	0	0.1	0.2	0.7	0.9
Densipolic	0	0.6	0	0.1	0.2	0.5	0.6
Lesquerolic	0	0.2	0	0	0.2	0.2	0.6
Auricolic	0	0.1	0	0	0	0.1	0.1

The results in Table 2 show that expression of the castor hydroxylase in transgenic *Arabidopsis* plants caused a substantial increase in the amount of oleic acid (18:1) in the seed lipids and an approximately corresponding decrease in the amount of linoleic acid (18:2). The average amount of oleic acid in the six transgenic lines was 29.9% versus 14.7% in the wild type.

The precise mechanism by which expression of the castor hydroxylase gene causes increased accumulation of oleic acid is not known. However, an understanding of the mechanism is not required in order to exploit this invention for the directed alteration of plant lipid fatty acid composition. Furthermore, it will be recognized by one skilled in the art that many improvements of this invention may be envisioned. Of particular interest will be the use of other promoters which have high levels of seed-specific expression.

Since hydroxylated fatty acids were not detected in the seed lipids of transgenic line 1-2b, it seems likely that it is not the presence of hydroxylated fatty acids per se that causes the effect of the castor hydroxylase gene on desaturase activity. Protein-protein interaction between the hydroxylase and the Δ12-oleate desaturase or another protein may be required for the overall reaction (e.g., cytochrome b5) or for the regulation of desaturase activity. For example, interaction between the hydroxylase and this other protein may suppress the activity of the desaturase. In particular, the quaternary structure of the membrane-bound desaturases has not been established. It is possible that these enzymes are active as

dimers or as multimeric complexes containing more than two subunits. Thus, if dimers or multimers form between the desaturase and the hydroxylase, the presence of the hydroxylase in the complex may disrupt the activity of the desaturase.

Transgenic plants may be produced in which the hydroxylase enzyme has been rendered inactive by the elimination of one or more of the histidine residues that have been proposed to bind iron molecules required for catalysis. Several of these histidine residues have been shown to be essential for desaturase activity by site directed mutagenesis (Shanklin et al., 1994). Codons encoding histidine residues in the castor hydroxylase gene will be changed to alanine residues as described by Shanklin et al. (1994). The modified genes will be introduced into transgenic plants of *Arabidopsis*, and possibly other species such as tobacco, by the methods described in Example 1 of this application.

In order to examine the effect on all tissues, the strong constitutive cauliflower mosaic virus promoter may be used to cause transcription of the modified genes. However, it will be recognized that in order to specifically examine the effect of expression of the mutant gene on seed lipids, a seed-specific promoter such as the *B. napus* napin promoter may be used. An expected outcome is that expression of the inactive hydroxylase protein in transgenic plants will inhibit the activity of the endoplasmic reticulum-localized Δ12-desaturase. Maximum inhibition will be obtained by expressing high levels of the mutant protein.

In a further embodiment of this invention, mutations that inactivate other hydroxylases, such

as the *Lesquerella* hydroxylase of this invention, may also be useful for decreasing the amount of endoplasmic reticulum-localized Δ12-desaturase activity in the same way as the castor gene. In a further embodiment of this invention, similar mutations of desaturase genes may also be used to inactivate endogenous desaturases. Thus, expression of catalytically inactive fad2 gene from *Arabidopsis* in transgenic *Arabidopsis* may inhibit the activity of the endogenous fad2 gene product.

Similarly, expression of the catalytically inactive forms of Δ12-desaturase from *Arabidopsis* or other plants in transgenic soybean, rapeseed, *Crambe*, *Brassica juncea*, canola, flax, sunflower, safflower, cotton, cuphea, soybean, peanut, coconut, oil palm or corn may lead to inactivation of endogenous Δ12-desaturase activity in these plants. In a further embodiment of this invention, expression of catalytically inactive forms of other desaturases such as the Δ15-desaturases may lead to inactivation of the corresponding desaturases.

An example of a class of mutants useful in the present invention are "dominant negative" mutants that block the function of a gene at the protein level (Herskowitz, 1987). A cloned gene is altered so that it encodes a mutant product capable of inhibiting the wild type gene product in a cell, thus causing the cell to be deficient in the function of that gene product. Inhibitory variants of a wild type product can be designed because proteins have multiple functional domains that can be mutated independently, e.g., oligomerization, substrate binding, catalysis, membrane association domains or the like. In general, dominant negative

proteins retain an intact, functional subset of the domains of the parent, wild type protein, but have the complement of that subset either missing or altered so as to be nonfunctional.

Whatever the precise basis for the inhibitory effect of the castor hydroxylase on desaturation, because the castor hydroxylase has very low nucleotide sequence homology (i.e., about 67%) to the *Arabidopsis* fad2 gene (encoding the endoplasmic reticulum-localized Δ12-desaturase), the inhibitory effect of this gene, which is provisionally called "protein-mediated inhibition" ("protibition"), may have broad utility because it does not depend on a high degree of nucleotide sequence homology between the transgene and the endogenous target gene. In particular, the castor hydroxylase may be used to inhibit the endoplasmic reticulum-localized Δ12-desaturase activity of all higher plants. Of particular relevance are those species used for oil production. These include but are not limited to rapeseed, *Crambe*, *Brassica juncea*, canola, flax, sunflower, safflower, cotton, cuphea, soybean, peanut, coconut, oil palm and corn.

CONCLUDING REMARKS

By the above examples, demonstration of critical factors in the production of novel hydroxylated fatty acids by expression of a kappa hydroxylase gene from castor in transgenic plants is described. In addition, a complete cDNA sequence of the *Lesquerella fendleri* kappa hydroxylase is also provided. A full sequence of the castor hydroxylase is also given with various constructs for use in host cells. Through this invention, one can obtain

the amino acid and nucleic acid sequences which encode plant fatty acyl hydroxylases from a variety of sources and for a variety of applications. Also revealed is a novel method by which the level of fatty acid desaturation can be altered in a directed way through the use of genetically altered hydroxylase or desaturase genes.

All publications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications are herein incorporated by reference to the same extent as if each individual publication was specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

WHAT IS CLAIMED IS:

1. A method of altering an amount of an unsaturated fatty acid in a seed of a plant comprising: decreasing a fatty acid desaturase activity in the seed by genetic manipulation of at least one of fatty acid desaturase or fatty acid hydroxylase.

2. The method of Claim 1, wherein an endogenous gene for said fatty acid hydroxylase is mutated and thereby decreases fatty acid hydroxylase activity in the seed.

3. The method of Claim 1, wherein said plant is transformed with a nucleic acid containing a sequence which encodes a fatty acid hydroxylase or derivative thereof.

4. The method of Claim 3, wherein said derivative is a dominant negative mutant which thereby alters the amount of the unsaturated fatty acid in the seed.

5. The method of Claim 3, wherein said derivative is a mutant fatty acid hydroxylase in which one or more essential histidine residues have been mutated which thereby alters the amount of the unsaturated fatty acid in the seed.

6. The method of Claim 1, wherein an endogenous gene for said fatty acid desaturase is mutated and thereby decreases fatty acid desaturase activity in the seed.

7. The method of Claim 1, wherein said plant is transformed with a nucleic acid containing a sequence which encodes a fatty acid desaturase or derivative thereof.

8. The method of Claim 7, wherein said derivative is a dominant negative mutant which thereby alters the amount of the unsaturated fatty acid in the seed.

9. The method of Claim 7, wherein said derivative is a mutant fatty acid desaturase in which one or more essential histidine residues have been mutated which thereby alters the amount of the unsaturated fatty acid in the seed.

10. The method of Claim 1, wherein said plant is selected from the group consisting of rapeseed, *Crambe, Brassica juncea,* canola, flax, sunflower, safflower, cotton, cuphea, soybean, peanut, coconut, oil palm and corn.

11. A method of altering an amount of a unsaturated fatty acid comprising:

(a) transforming a plant cell with a nucleic acid containing a sequence which encodes a fatty acid hydroxylase or a dominant negative mutant of fatty acid hydroxylase or a dominant negative mutant of fatty acid desaturase,

(b) growing a seed-bearing plant from the transformed plant cell of step (a), and

(c) identifying a seed from the plant of step (b) with the altered amount of the unsaturated fatty acid in the seed.

12. The method of Claim 11, wherein said nucleic acid contains a sequence which encodes the dominant negative mutant of fatty acid hydroxylase in which one or more essential histidine residues have been mutated.

13. The method of Claim 11, wherein said nucleic acid contains a sequence which encodes the dominant negative mutant of fatty acid hydroxylase which thereby alters the amount of the unsaturated fatty acid in the seed.

14. The method of Claim 11, wherein said nucleic acid contains a sequence which encodes the dominant negative mutant of fatty acid desaturase in which one or more essential histidine residues have been mutated.

15. The method of Claim 11, wherein said nucleic acid contains a sequence which encodes the dominant negative mutant of fatty acid desaturase which thereby alters the amount of the unsaturated fatty acid in the seed.

16. The method of Claim 11, wherein said plant is selected from the group consisting of rapeseed, *Crambe*, *Brassica juncea*, canola, flax, sunflower, safflower, cotton, cuphea, soybean, peanut, coconut, oil palm and corn.

17. A recombinant nucleic acid suitable for use in Claim 1, wherein said nucleic acid contains a sequence encoding a fatty acid hydroxylase with an

amino acid identity of 60% or greater to SEQ ID NO:4.

18. The recombinant nucleic acid of Claim 17, wherein the amino acid identity is 90% or greater to SEQ ID NO:4.

19. The recombinant nucleic acid of Claim 17, wherein the amino acid identity is 100% of SEQ ID NO:4.
